Robert made some pretty poignant comments about how many of the traditional methodologies don't really apply here, but notwithstanding that I would argue that our report cards actually are being built for the companies. Investors are just looking at others matrices, if you will. And then [I will] briefly touch on what's happening in the M&A marketplace.

This is a slide which depicts what's happened over the last 24 months with financing of technology companies.

In 1993, some 11.4 billion dollars were raised for companies in about 228 transactions. As you can see, in the fourth quarter it stepped up to around 5 billion dollars, and that was really when things really started to take off as far as the markets were concerned. This year, year-to-date through October, there has been about 20 billion dollars that's been raised, and the pace suggests that the fourth quarter will equal that of the third, making roughly 25 billion dollars, and probably it will be best year on record for financing growth companies. Feeding this growth has been the performance of the market underneath it, and investors keep coming back and asking for more because the returns are extraordinary.

This chart depicts the returns that investors have seen on three lines. It's a little difficult to read, but the bottom purple line is the S&P 400, the yellow is NASDAQ, and the top line is a composite of all of Montgomery's technology clients.

It begins in December of '93 and extends through to the present. I will focus my comments briefly on this year. Were you to invest a dollar in the S&P at the beginning of the S&P 400, you'd have about \$1.23 today in your pocket. The NASDAQ would give you about \$1.35, and the technology composite would give you about 2 bucks. You'd double it. In that, when compared to the S&P it's a 50% increase in rate of returns. That's why investors are coming back.

I would note that cautionary trend toward the top you see on the right; that curve is flattened, there has been a cyclical rotation out of technology stocks of recent date, primarily due to valuations, and we're going to have to see where things go. But as I indicated at the top I think the fundamentals for the economy are very strong, and I think investors are going to be continuing to fund these areas.

So in 1995, what are we seeing? I like to think of 1995 from the market standpoint as the first year of the Internet. Obviously there was some activity in the public markets prior to that, but if you were to look at a slide of who is involved in the public markets in 1994 it would be a much shorter list, and this is just a sampling of the companies. There is lots of ways to examine this, and cut and slice it and dice it, and I think that Bob did a pretty good job of kind of putting up the valuation parameters and how to organize things. You can look at them by software companies, networking companies, ISPs and the like. I tend to look at this from a different play, from trying to understand who investors are valuing this arena from the pure plays, companies like Netscape, Spyglass, PSI, EUNet and NETCOM, and those who I would argue are leveraging, for market and business reasons, a play on the Internet: [Harbinger], [Premanose], Checkfree, Dollarbox and the like.

One thing that I think everyone should keep in mind here is that while the universe is increasing, this year there are dozens of companies, and next year there will be multiples of that. The universe really is still very limited for public market investors, and I think that's one of the main reasons today that valuations are where they are for these companies. There is a scarcity, and you folks have a supply/demand advantage that you have in your back pocket right now. It's going to continue for awhile, but all good things will balance as far as the supply/demand is concerned in the future.

Just taking a look at the returns as each one of these segments is offered — most of these pretty quickly — but here we have the ISPs plus AOL, and obviously the returns in the red line are well in excess of what you would find in either the Dow or the NASDAQ this year. For the Internet software market, companies like Adobe, Firefox, etc. — again, well outpacing what the market has seen. Finally, with some folks that are related to the Internet, the equipment suppliers; people like Ascend, Cascade, Cisco, etc. have significantly outperformed the market this year.

So if we take a minute and we look at them just as select subset, what do you see here that has been the performance year-to-date? First of all you see that on average these companies have returned this year about 180% return to investors.

Compared with that technology index that I offered earlier, 200%, sounds like it's in line, but you got to keep in mind that these companies waited an average of being public six months, not the ten months that we have experienced so far; so if you kind of try to do an "apples-to-apples," you'd see that these companies' performance is up nearly about 60% over the tech index. And I think that is probably in line with the kind of risk/return profile, because many of these companies still are very young. They are losing money at present, and face a number of competitive threats that we discussed earlier.

So what are investors really trying to understand? Excuse me. One thing that I'd like to note here is that the amount of money that's been raised has been relatively small for financing. Today, as I mentioned, there is about 20 billion dollars which is being financed in public tech companies this year; for these five companies only 325 million has been offered to them. Their aggregate revenues are something less than 100 million dollars, and their market capitalizations are an extraordinary 5.9 billion dollars. So on a market value-to-revenue basis, it's a number that's off the chart. I call it "nosebleed territory." So you have to ask yourself the question: What are investors trying to understand, and how are they going about looking at these?

And I would say that where the Internet is today you can't use the traditional valuation matrices that we have talked about, that Bob alluded to these earlier. But what investors are doing is looking to have early evidence that the business model is in fact working. In the case of an Internet service provider, how fast is the Network being deployed? What is the cost of acquiring a subscriber? What is the performance of that network? And then there are the intangibles; is there any kind of independent or industry validation of a company? The best example here on the service provider side is obviously Microsoft's relationship with UUNet. UUNet is, by a couple measures, a smaller network than each of its purely public competitors, but its market capitalizations are a multiple of theirs, and that is because of potential that Microsoft is bringing to that equation.

Over on the software side it's the same sort of things you can do. On market acceptance, look at Netscape as a great example of where the user market really has embraced Netscape as a market leader. I'm not going to go so far as to say anything about a standard, but it's perceived in the public marketplace as being a market leader.

In this alliance and strategic relationship framework you can look at Spyglass, Microsoft, FTP and Open Market as other examples of independent verification.

The valuation matrix — I'm not going to dwell on this because I think Bob did a good job of touching on this earlier, just saying that none really apply. A few of them are starting to have a little bit of focus, and I guess I'd direct your attention on the service providers to the expected revenues. If you look at PSI and NETCOM you see that they are trading on '96 revenues in the four to four and a half times area; it's starting to coalesce on a number there, but because of the relationship that UUNet has they are trading at something in the order 13 times — so again, that strategic relationship and the potential that brings to it far outweighs the projected revenues, using that as a standard valuation matrix.

What's happening on the M&A front? I guess I would characterize it as one that is accelerating, and driven by strategic thinking as opposed to financial thinking at this point. These companies are jockeying to fill in key product services or technologies that they don't otherwise have. Valuations again are not being based on financial matrices; however, I would argue that there is an open issue here, which is that the companies can go out and make the acquisitions, and these oftentimes are done under what's called "purchase accounting." And when you're paying the kinds of valuations that you see for some of these transactions, a fair amount of goodwill is going to be created and recorded on the balance sheets of the acquiring companies.

I mentioned that investors are establishing report cards, and they are going to look over the succeeding quarters — and more likely years — to see how well that acquisition is being integrated. Is it creating enough value on an earnings basis to earn the goodwill and be an addition to the companies earning potential?

I'd like to have just a couple of thoughts here on this summer. First of all, the Internet is, as witnessed by the activity here today, the most exciting thing that I think that the public market has; if it's not the most exciting, it's certainly one of the most exciting opportunities that the public market is experiencing today, because it fundamentally offers a way to change the way we communicate with one another, and the way we do business and the cost structures associated with that.

That's why investors are paying the kinds of valuations that they are today for these companies. I think I've made the point that today the traditional valuation matrices do not apply, but they will. These companies all will go back, as Bob noted — they will be valued on an earnings basis, and they'll be valued relative to their growth rate. So if a company has a sustainable growth rate of 30% on a secular basis, its PE will be plus or minus 30 times forward earnings, and that's what we should expect in the long term.

The M&A arena is accelerating, it's very aggressive right now because it's strategic. Companies are filling in the holes in their product and service offering, but investors are taking note and will be looking to see how these acquisitions actually work out.

The question you ask yourself is: How long will the honeymoon last here for the Internet? And I think, really, that's a question to you. Investors establish report cards, as I have indicated, and as long as the companies that are in the public arena meet or exceed those valuation or those report cards, I think that there is going to be ample capital available for those companies. What will be the problem is when companies disappoint. And today, because of the massive amount of capital that's available and that is institutionally invested, it moves with lightning speed, faster than the Internet. It's amazing how fast people will move in and out of segments. So if you see a wholesale disappointment in a particular sector, don't be surprised if there is tremendous volatility in this arena as far as valuations are concerned.

Also, by the same token, if you see that companies are exceeding these expectations, I think you will find that these valuations are supported for the long term because of the tremendous opportunity that these companies and you folks represent to investors. Thanks very much.

[Timothy Duncan]: I think what we will do is take some questions for a few minutes and then take a break for about 15 minutes, and come back with the last three speakers for the afternoon. Any questions? Mark Walsh is the only guy that brought a checkbook today, and he has conveniently got up and left, he had to catch a plane.

M: Yeah, I have question. [Inaudible].

[Panel]: Well this is America, and it's all being valued by the markets out there. There are private markets as well as public markets. Your question is, how do the private markets value companies? There is a mania in the private markets just the same way there is in the public markets; there is a lot of money flowing into alternative assets and people are looking for quick returns, and there are a lot of people throwing money into private companies hoping that they'll just go public in six months and they'll make ten times on their money.

In the Internet segment, there has been an enormous increase in valuations over our traditional matrices. But it's a buyer and a seller, it's whatever makes sense, and we as a venture firm sometimes struggle to justify the valuations. Often we walk away from deals that are just great deals — but they're talking 100 million dollar valuations when we would normally put maybe 20 million dollar valuation on it.

[Timothy Duncan]: Any other questions before the break? Great. We'll pick it back up in about 15 minutes. Thanks.

[Tape change]

Timothy Duncan: Peter's company is a legal and consulting firm that helps both large and small companies establish strategic relationships in the on-line interactive and information services industries. His services include strategy, positioning, determining target partners, making contact and negotiating and structuring formal and informal relationship agreements. He's going to talk a little bit about what the Internet strategies are for the major on-line companies, how can Internet entrepreneurs position themselves to take advantage of these strategies, and what type of relationships are being structured in the current environment. Peter Marx.

Peter Marx: Thanks, Tim. As Tim said, basically I am in the business of helping companies get a strategy, basically figure out how alliances fit in that strategy — who should be the best partners, what type of deals would work with those partners — and help them structure that type of relationships and close the deals.

I'm going to do this from the point of view of kind a hypothetical case study. I'm taking something I'll be calling "*Tennis Universe* magazine" and I'll talk about their strategy and positioning, some of the potential partners they could be talking to, some selected strategic alliances that those partners have entered into, how to pick partners and how to structure relationships with them.

Tennis Universe magazine: What does it have? It's got two million readers, a recognized name, editorial and product databases and search software for feeds, and it's particularly tailored to the type of contents that they are interested in. There are strategies to become the place for tennis-related information, advertising, announcements, discussions and transactions. It's clearly a strategy that you can't fulfill if you're a print publication.

I've just selected a few potential partners, just to give you an idea of the way deals are being structured and how to think about it. Obviously there are many others, and these are the companies that I selected to look at for having *Tennis Universe* set up its own Web site.

[We'll] start with America Online. Now, in terms of acquisitions they've been very busy lately; one could call them an Internet mutual fund. Even if you don't think that their current model of doing business is going to survive, they're probably a good play on the Internet just because of the type of companies that they've been joining with. What is their strategy? Well, I view it as kind of an on-line community, and now they are linking into the Internet. I mentioned some of their game partnerships up there, because if *Tennis Universe* is in the tennis business it may be the people are going to set up on-line tennis games, or maybe the type of people that play tennis are going to be interested in on-line games more than your average person.

Some of their distribution agreements — basically about 20 computer companies that they've packaged their software in — kind of an answer to Microsoft putting Microsoft Network in Windows '95. The airplane [in this slide] is, as Mark mentioned earlier, the AOL airplane, and my thought here is that they could fly over the U.S. Open and drop floppy disks down to the people that are viewing that.

Content alliances. Well, first of all they are pushing very hard for exclusives. That's because they are concerned about everybody going to Microsoft Network and everybody going on to the Internet, I don't think that they've been that successful at it, but they have pushed hard on it. Some of the partners: Relevant, Reuters, *Time* and some of the sports ones that might fit in with a tennis publication. Obviously, if you're in the legal business or if you are in a different type of business you'd look at some of their other relationships to see how they are structuring things and whether it's the type of community that you think your business fits with. Mark talked about the Greenhouse; one of the Greenhouse partners is I-Golf, which would possibly seem to fit, with *Tennis Universe*.

How are they structuring their revenue sharing? Well, first of all, these vary a lot, but these are kind of numbers that are bandied about: they keep all of the basic monthly fee; with excess usage, they're giving the first numbers with the publisher — in this case the partner could be software — and they pay a bounty if new users come in because of your service. Ad revenue is 85/15, 90/10 on transactions, meaning if you're going to sell tennis racquets and people can order them on-line, but you obviously can't deliver them on-line, you're driven off-line — a 90/10 split.

The next potential partner that *Tennis Universe* could consider is Microsoft Network, and I look at it as a seamless Internet integration and the vehicle for electronic commerce. That's not real important today, but everybody thinks the big bucks are out there at some

point. They've been in the content business a long time, and are one of the leaders in the CD-ROM area. There's a big benefit in partnering with Windows '95, and the fact that Microsoft Network is bundled in it gives you a chance to hit a lot of people, 50 million potential users.

On the other hand, although we haven't heard much lately there is still the anti-trust questions that potentially could slow Microsoft down; if they do, they're not nearly as valuable a partner. Their revenue sharing numbers: 70/30, 80/20, and 95/5. Once again, these are just ballpark, and they're really negotiating all over the lot.

They're selling Web links, so you don't have to be on with them, you can just link them to your Web site. Then you have to decide: Is it better to have it from Microsoft, or *Pathfinder*, or somewhere else? Some of the alliances that they've got have individual links, local custom news providers.

TCI was an early investor, and they've got their Internet acquisitions. Some of the other partners [I've illustrated here] down below; they have a lot of content partners. Supposedly they are not coming on quite as quickly as they anticipated, but there is a long list.

Next company that *Tennis Universe* could consider is AT&T Interchange. There's a lot of benefits to partnering with them. AT&T has a lot of efforts going on. Business Network recently released a sister division to Interchange, and they've got partnerships with Netscape and BBN Planet for Internet access. They are also in the game business and soon they're going to be in the local service business. Currently AT&T always has to be considered as a partner.

The Interchange strategy is a brand publisher's platform. What I mean by that, is as opposed to America Online, where you kind of look like everybody else, is that the idea of Interchange is that you as a publisher can keep your identity, which is pretty important to a company like *Tennis Universe*. Some of the alliances they've got are with the *Washington Post* and [Gardner Groups]. Ziff Davis originally developed the Interchange, and part of the deal when they sold it to AT&T was that Ziff Davis would keep its computer publications, — *PC Computing* etc. — up on Interchange.

There are also some other newspapers, etc., and AT&T has said it doesn't plan to own content, which may be concern if you're worried about your partner competing with you; on the other hand, *Tennis Universe's* potential market is probably not big enough that AT&T is going to go after them anyhow. Bell revenue splits: 70/30. They take, once again, all the monthly fees, overtime connect by 95/5, ad revenues 85/15.

Once again, the publisher retains their brand identity. They evidently don't have Internet access, which is clearly a big "E" to this audience and to most people these days; they expect it in the summer of '96, which is kind of a lifetime in the current environment.

NYNEX. I mention them here as kind of representative of the Baby Bells. We all know they dominate voice telephone and they have great potential to become a significant Internet access player. ISDN, which has had significant potential for years, is much more important now that people [are] looking for more speed; and particularly with the broad networks this is going a little slower than everybody anticipated.

What their strategy is, heaven knows, and that pretty much goes for all seven of the Baby Bells. At any rate, they are not in any position now to play a significant role. They have to do some acquisitions, and time will tell what those are. They do have the money to do it, so somehow or other they say that they want to be player. One of the alliances they have done is InfoLook, which was a gateway service. [Judge Green], who manages the area which regulates the Baby Bells, gave them a little bit of permission to get in the information services business — but not enough to do anything meaningful, and that closed down, as did most of the Baby Bells' gateway services.

Our Dow Jones, a financial news wireless service, closed down [their Internet project]; and News Day was a home shopping experiment which didn't work out. They do have a relationship with Prodigy, both for directory information as well as for some network services.

Partnership with Bell Atlantic for wireless. They were very big in acquiring computer companies several years ago, but virtually all of them have been divested by now. They said they wanted to be in content, and their first major foray into this was a 1.2 billion investment in Viacom. Pretty much what they bought was a seat on the board and the ability to talk about synergy. We haven't seen much results on this so far, but they're not in battles with their partner, like U.S. West and Time Warner.

Bell Atlantic, Pac Tel, and Creative Artists have a 300 million dollar joint venture which kind of took — well, had bad news when Michael Ovitz went over to Disney, so this is probably not going to go too far, but the intent was a major play in content. Once again, this is entertainment content rather than information content.

The possibilities NYNEX had for *Tennis Universe* are really interesting. NYNEX Information Resources — this is a Yellow Pages subsidiary. It's a billion dollar business, very profitable, and they have a vast consumer information database; they have their sight set on electronic commerce, and this would certainly work well with *Tennis Universe* being a small subset of that. The strategy isn't totally clear today, and they really can't play the game until there is regulatory relief, but at least from this point of view they are a partner to be considered.

How about setting up your own Web site? Everybody here is probably doing it or thinking about it. It's a large audience, you have a lot more control, you got a managed infrastructure. You can go for all the revenue opportunities, and you dictate how. Challenges are security, [the fact that it] is a lot tougher than going with one of the proprietary services, there's a lot more development and marketing, which is a big deal.

Once you're out there *Tennis Universe* is a small player, so it's probably easier to communicate with the America Online membership than it is to communicate through marketing with everybody that's tapping into the Internet.

And then, finally, you have that risk that everybody has: are consumers going to pay for anything here? Is it all advertising-driven, and would that be enough to pay for this?

Some of the issues impacting the market positions of all these players impact whether you want to partner with them. Broadband network play probably will impact NYNEX, the [Artbox] and AT&T the most. These are going much slower than everybody thought, and it's a lot more expensive, a lot harder, and there are still more questions about who's going to pay to bill them.

Telecom deregulation. Everyday we read about the battles on this, and I think it's coming and that's going to certainly open up things for the Baby Bells, but it will take them time to get into the game.

Convergence. Who is going to be the winner? All these different industries merge together, and you want to partner with whoever is going to be the winner.

The Internet is a tool, certainly, and you can do anything; it will be shortly that you can do it on a proprietary service on the Web, but there is a lot of challenges in picking [which one] — who's got what, what's going to survive, and what's going to be the standards?

And I think extremely important is this Internet business model. A couple of people have mentioned that, and you can look at it different ways. To me there is no model. I assume it will evolve, but it's unclear what type of services work on the Internet, and whether anybody will pay. And if it's only advertising-driven, there is an awful lot of businesses that just won't work, I think.

Factors in picking among the partners: market reach, including the Internet access; and the revenue splits I think are less important in terms of partner picking, because I believe that despite the numbers I put up earlier they all negotiate, so that there are no fixed rules on that.

Time and financial investment, once again, are really not much different. All of them are ready and anxious to deal, except for NYNEX which can't, and that probably puts them out of the game.

Technological strength: they've all got strengths and weaknesses, and you have to take a look at what your business is. For *Tennis Universe* I put down that they have this search software, though it's probably not as sophisticated as anybody up there as a potential partner; on the other hand they have some things that fit in tennis, *Thesaurus* and so fourth, that are particularly geared to their business.

Infrastructure. Everybody is building and they infrastructure all these type of things. Some are a little better than others, and they'll all get there, I would think, pretty quickly in order to handle these type of issues.

The payment one is a little harder on the Internet, as we all know.

Structuring the relationships. What counts? Some of the key issues are operational, like any joint venture alliance.

Cultural fit, I think, is the first thing. If you walk in and you start negotiating and you don't feel comfortable with the people, regardless of the strategy it probably won't work out for some reason or other, and I think that's a lot of the problems that the Baby Bells are having with their media partners. There is just no cultural fit. My feeling is that the most significant expense by far is to whether people are capable of doing the marketing you need — who's going to pay for what.

Development. On the proprietary services, just a little bit development is needed as opposed to on the Internet, and it's probably less important in marketing.

Security is a big issue; on the Internet less so, all the services are probably pretty secure.

Financial royalty splits. Microsoft made a great to-do over the fact that they had turned the equation around when they were coming out with Microsoft Network. Basically they said, "hey we're going from you the content owner getting 20% and we'll take 80% reversing that to 80/20, 70/30, so you got to make a lot of money on Microsoft Network." I don't know where they get their figures from, I don't believe that it's been anything like that. I think that, first of all, if you look at the commercial side, the content owners are far bigger than the people that are distributors, and obviously if you look at Dow Jones, Reuters, Dun and Bradstreet, they are far bigger than Lexis/Nexis, Dialogue or any other consumer things, and basically the splits have been negotiated on the basis of bargaining power.

I think the splits have been pretty good for the content owners. The mass market is so new, for anybody to say "this is the formula" — well there hasn't been any formula, it hasn't been around for long enough for there to be any significant splits, and they've always been negotiated and they still are today, so it's nothing like the content owner is taking 20% of the total revenue package on Microsoft Network. So I think it's very much and always has been heavily negotiated, and will continue to be for the foreseeable future.

Expenses. As I said, I think marketing is the only one you really have to worry about, how that's going to be shared.

What's going to be the biggie? Legal. A lot of people we have here will talk about legal, maybe not in this context, maybe contracts — although on the Internet there may not be as many contracts as we had in other arenas, but that is part of it. Who's got the customer connection, who's got the identity, are very important to structure a deal, so that you continue to own your customers.

Protecting intellectual property is a big issue. Everybody — and it doesn't matter where you are — I think that unless you have content or a service that is constantly updated at low cost per unit, intellectual properties continue to be a problem, and I don't think encryption and a lot of other schemes are going to work for quite a while. So people are a little bit shifting the type of business that they are putting out there in order to take this into consideration, kind of for better or for worse. The business models are shifting in order to face this problem.

Exclusivity. I think the last major exclusive deal was the *New York Times* did a long-term exclusive with Lexis-Nexis with regard to its historical information. It was viewed by most people as a disaster for *New York Times* when Lexis/Nexis was sold out of the air; they terminated that, it was the first opportunity they had. I don't think we are going to see anymore major exclusives of that sort, and I would certainly say for *Tennis Universe*, don't enter into an exclusive despite the fact that Microsoft Network would like you to, AOL would like you to. On the other hand maybe you can tell me you won't go on Microsoft Network for awhile, and that may be sufficient.

Who is responsible for these issues of liability, privacy, pornography? We're reading all these interesting cases in the paper, but the issue is not when the distributor or whether the owner of the service has done something wrong. It's more of the Prodigy and Stratton-Oakmont, where some third party has done something wrong. How do you figure out between the two of you that this is worth negotiating on? It's a very hard negotiation, but the stakes are very large, and we're going to see a lot litigation in this area. I'd say deals used to be three year terms with year-to-year extensions; I think they are getting shorter and shorter, just because everything is moving so fast. Nobody wants to tie themselves up very long.

Some conclusions: I think set up your own Web site. *Tennis Universe* is a small player but everybody is capable of doing it today. Perhaps take one partner among these. NYNEX is not a possibility today. Other than the Internet issue, probably AT&T interchange would be a real good partner for *Tennis Universe*. Microsoft is certainly going to be a big player, America Online is already there. For somebody like *Tennis Universe* that isn't there already, it's probably pretty good to tap in to AOL; you have two and a half million users and it's growing fast, and just tell them: "Hey, we won't go on Microsoft Network for a year, but we have to have our own Web page," and in effect you do your market research there. If it's a good business you stay there, if not then you just go to your Web page and maybe another distributor.

I don't think you have the time or the money to deal with more than that. Some of the deal points that I'd negotiate with them is the non-exclusive, obviously the ability to set your prices — a lot easier on your Web site than otherwise, and pretty much easier with AT&T Interchange than it would be with AOL, because they've got their own structure. Keep a fair share of the revenues, what ever the heck that means. I guess my point here is that it's negotiable; you don't have to take any formula, you have to set up your own business motto and what's going to work for you, and I think you can negotiate to get that with any of the players. Maintain the primary customer contact; as I was saying before, once again it's easier with Interchange than some of the others.

You've got it totally on your Web site, so protect your brand identity. Once again, a player *Tennis Universe* has to do that. If you're somebody in a different type of business maybe you don't care, but I would say for this type of a partner you have to insist that that's the way it is, and anything a partner can do to help you maintain is really a critical bargaining point. Thank you.

[Panel]: I think anybody that reads the newspaper and is interested in the Internet has had a hard time, or would have a hard time not knowing who Forrester Research is. As a matter of fact I had this fantasy that if Jesus Christ returned to the planet and decided to communicate to

people over the Internet, you'd read in the *New York Times* the next day: "Jesus Christ returns to planet, communicates with people through Internet," and the next line would be "According to [Maria Madow and Listed] Forrester Research this was the first time a spiritual leader had decided to use the Internet for..."

[Panel]: We have been briefed on that, by the way.

[Panel]: But Emily Green is here today and Emily is with Forrester. She is a senior analyst there. She is part the group that looks at high-tech consumer markets, and to that end she follows the services in the Internet, and she is probably the only speaker here today with movie credits. She is an engineer and spent the early part of her career out in Hollywood designing special effects and to the effects for movies like *2010*, *Star Fighter* and *Ice Pirates*, so she is going to present an interesting perspective of our business. Emily Green.

Emily Green: Hello. Do you hear me, can you hear me? Yes, okay. Hi, thanks for inviting for to join you, this is a great group of people to be a speaker amongst. I'm not sure if that was the right preposition. Am I standing in front of everybody's view, can you see me? Yes, you can see, I know you can see. Anybody that want to move? No? Okay.

All right. As Tim told you I am an analyst with Forrester Research. I'm in the group called "People and Technology Strategies." That's kind of a mouthful, but we look at high-tech in the consumer markets, we cover the ad and the Internet world, but [the Internet world is] where I spend most of my time. To say I'm one of the only — well, at least a half a dozen analysts at Forrester look at the space, and none of us can see all of it at once, as hard as we try. But I think all of us would agree that being analysts we do know everything there is to know about this space and we have all the answers. I could definitely make it my life's work to answer phone calls from people who call me up and say "I'm going to start a business, and what should I do?" So it seems somewhat appropriate that I got asked to speak on the topic of "How do you make money on the Internet's space?"

Again, I can't take the whole Internet as my topic, partly because of the limits of time, so I'm going to pick out a couple areas where I think I can share some insight with you and see if I can tell you anything you don't know already. To do that I'm going to draw on some research that we've done recently, some of that I led myself and some done by other folks. Just to sort of frame the discussion, there is probably two sections to this talk. One is to at least get you to look at it from my point of view, so even if you don't agree with the landscape at least you know what my perspective is.

So we'll do a bit of a level-set first, and then to try and talk about where the return on investment can actually come from. For those of you who are not looking at starting you businesses or trying to get your own businesses off, [the question is]: Are there any more Netscapes out there? I don't know if I can answer that question, but I'll try.

Okay, so in terms of just doing a level-set here... Oh, yes, this is my disclaimer. I think we are going to talk about this question a lot, and I don't want to be associated with the idea that Forrester's whole point of view about the Internet is that it's a way to make money. There are a lot of things that you can do with the Internet. I just want you to know that I know that. I get a lot of questions on panels afterwards like "don't you understand all the other things you can do with the Internet besides sell advertising?" And yes, I do understand that, and that's not the subject of this talk. I just want to say that, to sort of put a fence around the context here. So there are a lot of other reasons to get [involved], there are a lot businesses that have a phenomenal opportunity to reach their customers or their suppliers through the Internet, and I'm not going to talk about it.

All right, a definition first. I'm just going to be economical and say — and please understand that I'm talking about the Internet, and I'm also talking about proprietary service. I'm talking about the wired world.

I'll just try and give you quick characterizations. I think there is an opportunity to do a "Leonard Pinth Garnell," the character from Saturday Night Live, who used to do a little segment on bad theater. I think in terms of looking at the content in the past, in both services and the Internet, we had a lot of bad stuff. We had bad brochures, bad catalogues and bad magazines — that is, adaptations of content from other media. I'm sure anybody who spent any time in this space has a well-thumbed copy of Marshal McLuhans' *The Medium Is The Message* book by [your night stand]. You look at this nightly before you go to bed, right? One of the things that he said was that in the beginning new media always looks like old media, and I think that's an example of what we've been seeing. Everybody's idea of what content should be is something that was borrowed from television or print and — "re-purposed" is the euphemism we use — putting it up on the Web, for instance.

Users. Definitely, the user probably should be visitors or subscribers, the people that you can reach through this medium. We definitely have an earlier adopter profile. Yeah, there are eight million American consumers that you can reach through the services on the Internet, but they have a narrow demographic. That's not a value judgment; that could be good or bad, depending on who you are. If you are the medium and you want to reach people who are 25 to 45, predominantly male, high income, users of technology, have PC, have high-end PCs at home, upgrade their PCs regularly, that's a great demographic segment. But if you're Neiman and Marcus it's not such a great demographic segment, because you need reach women, you need to reach people who aren't technically savvy.

So the narrow demographic of the people that you can reach through this in the past has been part of the problem, and also part of the opportunity for many businesses. In terms of the networks themselves, there was clear distinction between a proprietary commercial service like CompuServe or America Online, or Prodigy or Delphi or whatever. Consumers were forced to choose between one or the other of the on-line services, and services spend a lot of energy very carefully positioning themselves as "not the Internet." "We're not the Internet, we're more secure. We're not the Internet, we're more family friendly. We're not the Internet, we're easier to use. We're not the Internet, we're not so confusing." That's the old way, right? That's the way it used to be.

So things have changed a lot in the past year I would say, talking about the presence, basically just limiting ourselves to 1995. In the area of content I see a lot of reasons to hope for good things ahead. I see lots of interesting content that has been innovated or created specifically for this medium. I didn't hear Mark Walsh's presentation from AOL but he probably mentioned Motley Fools. Was anybody here to listen to Mark, did he talk about Motley Fools?

[Panel]: Not today.

Emily Green: No he didn't. I can't believe he passed up that opportunity. It's the first time I've ever gone on a panel with Mark where he didn't mention Motley Fools. Motley Fools is a very interesting space on America Online. It's not content — well, it is kind of content, it's a space where if you have an interest in personal finance and investments in the stock market you can go there and you can follow a portfolio that they've created, you can engage in conversations with other AOL subscribers about the various stocks that they pick. You can join moderated discussions about other segments of the stock market, and it's an experience that is not an adaptation of *Money* magazine. It's not an adaptation of Louis [Rukeyser's] *Wall Street Week*, it's its own thing created expressly for that medium.

In the Web there are two examples that I love, that I look at periodically, and one is the *Discovery Channel*. Does anybody look at that? Yeah, do you like it? I think it's an interesting place because they're creating content that is specifically for the Web. Yeah, they are affiliated with the network *Discovery Channel*, but these are the people that are cast with creating content for the Web space are separate.

For instance they are about to launch a new... This is such a stretch for words sometimes in this space — I always want to say “space and area,” — a new part of their Web site where they're going to be sharing information about a documentary that will not be seen on the television networks until a year from now. But meanwhile the community can watch the research that the scientists are doing unfold. As it happens, they engage in a dialogue with the researchers themselves.

Another interesting example on the Web is The Spot, has anybody seen the spot? It's interesting because it's not a TV show, but it's kind of like a *Melrose Place* of the Web. But it's not *Melrose Place*, it's a different experience. It's “multi-threaded episodic content,” I guess, for one of the better terms. But the idea of unique content is being created, and I think that's promising.

Obviously in the area of users there has been a phenomenal amount of growth, partly because of the blanket strategy that AOL has with the sketch but also because of the enormous amount of information that consumers have access to now in the press and television, fueled partly by organizations like Forrester Research. But there has also been a good deal of churn, at least from the consumer point of view. Consumers get on line and get on the Internet, and try and figure out what's good about it after they've been told by their neighbors or their brothers-in-law to check it out. They get on and try to understand how it's useful to them. How does this fit into my life? The same way a newspaper fits into my life? What's the benefit to me? And we see a lot of churn, and we suspect that's because people haven't yet understood what the utility is. There is a novelty factor, but the novelty wears off, the bills start to come, and they say “Ah, I'm not sure it's really worth the money.” So it's a problem.

In the Network area the services have gotten religion as a result of content, and consumers are starting to move toward the Web, as the Web is the easier place to put content up. And as content providers they can have more control, and can look like the way they want to look — instead of the way America Online wants them to look — and they can experiment with various models for revenue by charging fees or controlling their advertising.

Content is going that way; consumers see that that's where the really cool stuff must be, and so the services have not being able to afford to continue to make themselves distinct from that space. Now the services in effect are saying, “we're your gateway to the Internet, we're your characterization of the Internet, we'll help you figure out what's good, what's decent, what's valuable on the Internet.”

Of course, all of this is causing the Internet itself to wrestle with a lot of maturation problems like security, upload of popular sites, quality of service and the phenomenal appetite that surfers have for what people call “eye-candy,” and that is the multimedia sound and graphic stuff.

We're trying to figure out how to adapt the Internet to meet those appetites. So what's ahead — I'm not going to probably stun you with these revelations — but I think we haven't yet even scratched the surface in terms of interesting content. That's maybe a cop out, but again if I knew what the really great idea was I wouldn't be forceful, maybe I would be doing it. But I think that we're going to be laughing a couple years from now that the idea that the predominant content model for the WorldWide Web is magazine content. I think that's going to seem laughable. So I think that people are going to be coming up with some very interesting ideas, and I'm sure Mark mentioned Greenhouse as a place where they're trying to foster that.

And they're not alone in that area; all the of services and all of the large Web sites are fanatically trying to understand where the really creative content is going to come from.

Users. We definitely see an opportunity, we see a trend that's reassuring for all those people that want to reach something beyond the current narrow demographic. Definitely more women are coming, more children are coming, people who are less technically savvy are coming, and you're getting a little a bit of a spread in income in terms of consumer demographics. In the Network we see a lot of upheaval ahead, and we see that the networks are ultimately going to look lot like the long distance market.

Two reasons. One is we just don't think that a lot of these business will be able to withstand the downward pricing pressure that's created by the competition. There is the commoditization of access to the Internet that's upon us, and then what starts to matter in terms of being in that business is scales, how big you can be and how far you can drive your cost down. The other reason it's going to look like the long distance service is that the long distance players are going to be pretty heavy hitters in this space. AT&T and MCI are already starting to move in that area. So there will be lots of acquisitions and consolidations as that part of the market gets squeezed.

I just want to conclude this level-set with a couple Forrester figures which are freely quoted in everybody else's presentation for their own board of directors, and show up in business plans all over the world. These are relatively recent numbers that we just put together in September for a research report that we did called "The Internet Economy." Everybody is craning... Why don't we read the numbers out loud?

Oh, push it up, okay. Two charts here. One is a characterization of the penetration of PCs and access to the Internet in U.S. households in 1995 and the same assessment in the year 2000. Right now there are about 96 million U.S. households, so it's almost one for one year. Our numbers for penetration of home PCs in the United States are something like 24 million, which adds to about 28%, and our number on Internet access in U.S. households about 5.6 million, something like that. I'll tell you that these numbers tend to be very conservative compared to other figures; we see a lot of PC penetration numbers that are a lot higher. We actually account in our PC models for the retirement of machines. We are starting to see people on their second and third generations of computers, and we haven't seen anybody else's forecast that really takes that into account.

I'd just like to mention that because that tends to come up as a question pretty often. What we see in the opportunity for penetration and consumer space over the next five years is pretty strong, although we are certainly going to be far shorter for ubiquity, which is a nasty assumption I see in a lot people's pointers. We still think that by the year 2000 Internet on-line service access is likely to be below 25% in U.S. households. I think that's maybe a bit of cold water for a lot of people.

M: [inaudible]

Emily Green: Do I have — the question was, do I have a volume of [pillar] houses on the Internet? We have that number prior to the model that drove this chart, and I don't have it at my fingertips. So if you want to give me a card, we can talk later.

Okay, and one more chart and then I'm going to move and talk about the business model stuff. Also from the same analysis, this is our projection for the shift in sex and age of on-line users. In 1995 it's our assessment that overall men make up about 74% of consumers accessing the Internet and the on-line services. Now, that's a composite number, and what's very interesting it that it is being played up very heavily by some of the on-line services, and their numbers vary quite a bit from that.

For instance Prodigy has, I think, 42% women. That's very high, it's the highest of the on-line services as far as I know. Right now the numbers we have for children — that is, children under 17, under 18, 17 and under — about 4%. Our projection is that in 5 years we will see a shift where adult men will drop to about 50%, with the remainder split about 30% or 33% women and the remainder children. So there are growth opportunities in both women and children.

Now, return on investments... Here are some things I'm going to talk about and some other things I'm not going to talk about. I'm going to do a real brush on the infrastructure opportunity — that is, making money, as probably everybody in this room wants to do. So, you're all going to leave as soon as I'm done with that slide, right?

Routers, servers, browsers, that market. Selling equipment or services that are allowing this whole market to expand. I'm going to talk about revenue opportunities in content and in retail because that's part of what I personally track. There are a number of other revenue opportunities that I'm not going to talk about; I just want to make sure you understand that I'm not assuming responsibility to describe the entire universe of revenue opportunities.

Okay, infrastructure. What I'm going to do is give you some numbers that are part of a Forrester study done by another group inside Forrester; but before I do that I'll just frame it a little bit. We looked at the whole infrastructure opportunity in four sections: access, that's the Internet service provider business; hardware, that's selling iron to fuel the growth in that service; software, that's Web servers, Web clients, and tools; and services — sorry for the typo — and that's helping build your Web site, hosting a Web site, that sort of thing.

People are struggling to see. All right, you want me to read this off? That's rule number one in presentation school, never read your slide. Fortunately my presentation instructor is not here, so...

Access. We think there is a lot of up-side left in the Internet service provider business, but as I said I think it's going to be very competitive — which is not say that there is not a lot of dollars there, as small and medium-sized businesses come in to the Internet.

Hardware is definitely riding on the coattails of access. As more people come on board there are huge opportunities, primarily in servers and modems and other interface equipment.

Software. Yeah, there's opportunity there, but I think it's going to be very, very bloody. We see waves of features starting to hit and that really devalues the price of the software. We spoke earlier about the models of delivering excellent functionality for free, and it's tough to make a business on that. A professor of mine once called that "selling at a loss and making it up on volume."

All right, service opportunity, I think, will be relatively short-lived. I think a lot of people are using outside services because they can't find the skill set in-house or they can't hire the skill set because they are making too much money as consultants. I also think that there is a lot of upheaval in the tools area right now.

If you're going to build your own Web site development team, what set of skills would you want to hire? Well, this week it's HTML, next week it's — what? Who knows? As tool site jobs come out and are replaced by even more competitive offerings, it's going to be hard to pick a target in terms of equipping an internal organization. But I think that ultimately the tools issue will settle out, more people will get conversant with those tools, and the opportunity for consulting and other kinds of services will diminish over time. I'm not really relishing that. So here is the all important market size chart for those four segments, and since this is delightfully unencumbered by actual numbers...

[Tape change]

Emily Green: ...The hardware market we size in '95 at 50 million dollars, which is really small but growing by 2000 to 2.2 billion.

Services market is at 30 million in '95 going to 1.6 billion in the year 2000.

Access market we sized at 123 million — here, this doesn't include on-line services, because that's about 700 or 800 million on itself; this is just in-and-out access — 123 million in '95 and about 4.2 billion in the year 2000.

Software about 143 million now, expanding to about 2.8 billion by the year 2000.

Overall these four segments comprise about 350 million and about 11 billion dollars in the year 2000. Again, I think these are characteristic of other [inaudible] numbers, and they are relatively conservative relative to other projections I've seen.

M: [inaudible]

Emily Green: Yes, yes. Okay.

M: [inaudible]

Emily Green: We did split it in the model that underpins this chart, but I don't have the numbers with me. There is a very elaborate model that goes into this. Yeah, another question?

M: [inaudible]

Emily Green: That's an excellent question, I'll repeat it. The question is, does this model count or project the opportunity for just those components of the Internet itself outside the various corporate firewalls, or does it really reach through the firewall? And it does not reach through the firewall. This is just the Internet itself.

Yeah, one more question and then I'm going to move on.

M: [inaudible]

Emily Green: The question is, can I expend on the projection for access? I don't know the size of the long distance telephone market, but it's quite large. I didn't mean to imply that there is no revenue opportunity there, just that the competitive scenario is — what, AT&T has about 60%, MCI has about 30%, and Sprint and the others have the remaining 10%. It's just that there is not room for a lot of different competitors in the model. That's the analogy I was drawing.

I don't think that's saying it's going to look like long distance diminishes the revenue opportunity there. Okay.

All right, I'm going to move on; any other questions I can take afterwards.

All right, so I wanted to talk about content revenue opportunities. I wanted to sort of dispatch the infrastructure discussion pretty quickly. Again, we've done a lot of research in this area, and there are a lot of Forrester people that know a lot about it, so I'll be happy to point you in the right direction if you need more information.

Content. We recently looked at how to make money as a content provider. As a publisher for instance, how can you make money with your content in the WorldWide Web?

There are three sources for revenue for content providers: advertising, subscriptions, and fees paid — subscriptions and transactions, sorry, I'm going to lump those together — and fees paid to the content provider by, for instance, the on-line service in order to have the content, making the content available. We've been very bearish on the revenue opportunity for content in the on-line servers. We think that very few of them are really recognizing anything

other than a drop in the bucket relative to their expense to do this, and all it's providing is an exposure to the kinds of people they can reach, learning about the kinds of problems they have to solve and how to adapt their content, and the money that they can recognize through the payments of people like America Online just going towards partially offsetting their investment. But there is no big opportunity depending on America Online or Microsoft to pay you for your content. And again, no opportunity in the Web, right? There is nobody to pay you in that model.

The subscription and transaction model. We're not opportunistic about that. We don't think that that's a really good opportunity — again, I'm talking about consumers — all except the business model. But I think consumers in general are much more familiar with media that subsidizes its cost through advertising. And though lots of people like the public television model, when push comes to shove — and right now here in Boston WGBH is doing its annual fund drive, it's driving me crazy, I'm not listening to the station this week because I can't stand it — most consumers, when given the choice, will opt for content that's subsidized by somebody else in order to keep their cost low. And that of newspaper, television and every other media that they know and love. There definitely is a modest opportunity for people that have a very focused Internet goal, but in general we discourage people from trying to make a go on the subscription model.

We were talking about *Discovery Online* earlier; they came out with their Web site and announced that they were going to have the Web site available for anybody for 90 days, and then starting September 1st they were going to start to charge for it. They were going to have a subscription model and it was going to be, I don't know, \$24 a year or something like that. Well, they haven't really gotten around to implementing that, they [inaudible] started charging. I think their sense is that they're not sure that they can make the case to the individual visitor that that's a viable model. I think they are really interested in building a community right now, and that's another reason not to implement subscriptions. What you really want to do is build your audience.

So where does that lead? Advertising, right? We did an analysis, and this is going to be hard to see...

M: [inaudible]

Emily Green: All right, does that help? Advertising is the real revenue opportunity for content providers on the Internet; according to our figure, something like 2.6 billion dollars by the year 2000. Again, just to frame this, this is where we can find revenue, what the source of revenue will be for content providers in the on-line space.

Access fees from services and subscriptions and transactions revenue are extremely limited. It really is advertising. And when I talk about this to people who aren't maybe as wired as the audience, people bring up the Prodigy example of this sort of ticker-tape at the bottom of the screen; and advertising is undergoing a phenomenal transformation, and that's another presentation in itself.

But advertising as we know it is changing. Somebody earlier used the word "edutainment," and what we've been talking about is "advertainment." It's the same attempt to say that advertisers are trying to explore methods of making their advertising more appetizing, more interesting to people, and you have to think about the evolution of that. We're not talking about 2.6 billion dollars worth electronic billboard; we're talking about people who really figure out how to make this a way to connect with their consumers.

Okay, so I said I would talk about — oops, I have one more slide on content.

Is this a crazy forecast? Some people have said this is crazy, 2.6 billion dollars is an enormous number, and I just wanted to give you something to compare it to. Forrester's own projections about the number of consumers reachable in the on-line space by the year 2000 is something like 27 million. That means that we're talking about \$100 per capita by the year 2000 of advertising expenditure. Compared to what is expended in the print world in order to reach consumers, I mean the TV world, it's quite modest. So I just wanted to give you that context.

M: Is that an annual number?

Emily Green: Yes, that's annual, thanks.

Okay, now I'm going to talk about retail for the charge [inaudible]. We've looked at retail very recently and the best word for it, if you try to sum up the best opportunity to sell things to people through the on-line media, is it's experimental. Some people are making a big go of it and other people went in with huge expectations and are sinking and getting out fast, and I would say the predominant reality is that people that got in are slugging it out and aren't really making anything happen yet, but they realize that the opportunity now is to experiment, to understand, and if they can hang in long enough the up-side will be there. If you're successful right now selling on-line, it's because you have a product that's very well suited to the demographics.

I mentioned that it's a narrow demographic, it's predominantly male and they tend to be high-tech obviously, so the kinds of things that are selling well on-line are hardware and software. Buy a new computer, fire it up, get on-line and buy some more software for your computer. Other things that are selling well are what I call "bit" products. Anything that can be reduced to bits in some fashion seems to be a very close, a very easy step from the on-line medium itself, and that is books, music, CDs, videotapes, etc. These are also things that people are already comfortable with not necessarily going into a store to buy. And these are things that can be sampled on line; there are publishers that are sampling chapters of their books and tables of contents. You can access bits of soundtracks, and I think we're going to see lots more of that. And there are software organizations, people selling software that are actually delivering the software on-line. So those kinds of things are doing well.

The other thing that's important right now is an attempt to understand the best way to deliver value to the consumer, and that is an attempt to shortchange an enormous discussion of the fact that the consumer has lots of other opportunities to buy these things, these are products that they can buy elsewhere, frequently through direct-mail, almost always through going to an actual store. You have to understand exactly why they should buy it on-line, and you can't say it's because it's easier, because most of the time the truth is it's not easier to buy it on-line. It's not much fun after you've done it the first time.

So after they've gotten beyond the novelty of being able to send flowers to mom from the computer, you have to understand exactly why they are going to want to do it with you. Is it because — as in the case of Software.Net, the people that sell software on-line — is it because they've managed to capture a lot of your shopping experience in one site, that you can look at product reviews, you can access some manufacturer's pages, you can get on a bulletin board and you can talk to other people that have used it, and you can actually take delivery of the product? They've corralled the entire shopping experience for you at that site. Or is it because it's cheaper? There are not a lot of people yet that are offering products for less on the Internet, although I think ultimately that will change.

What's the point? There are a lot of people who just get on there and assume that it's the "build a better mousetrap" myth, that people assume that the world is going to beat the path to their door just because you can now buy diapers on the Internet, which you can. But

you know, it's not happening in a big way yet. What needs to happen for retail to be a successful business opportunity for people is this: the customer base really needs to diversify beyond the demographic we have now. I mean, the Neiman Marcus' of the world would love to use this as an opportunity; they see direct-mail, paper and postage costs [going] through the roof — it costs them a lot to put catalogs through the mail, and they realize that there is a developing backlash to junkmail, and consumers don't want to be bombarded with stuff. They would love to understand that this is the way that they can reach consumers.

But what needs to happen, of course, is a much bigger penetration into the consumer space. The shopping experience itself has to get better; it's pretty flat right now, it's not really as nice as looking at an actual catalog. And somebody said to me, "If you want a portable, random access, multimedia shopping experience it's a catalog, it's not the Internet or the Web at all." So you need to have more multimedia in the space, and that means better tools for developing those Web shopping sites, and it demands more bandwidth to the consumers so it really is the thing to watch as the pipeline to the consumers home expands. Those things will happen over time, but they're not there yet.

The other thing I like to talk about, that hasn't really happened yet, is a sense in the retailers of what merchandising means in this space.

Anybody that spent a lot of time in merchandising in the stores, in department stores, can tell you about all the research that they've done where they positioned people in the aisles to watch where people go as they wind their way through a department store. Grocery stores discuss where certain "for sale" products are going to be positioned, on which end-cap, to get your attention as you go down the aisle with your cart. There is no consensus yet about the equivalent of what an end-cap is in the on-line merchandising world. What's the value of a particular space on a page? Somebody back there really wants to ask a question.

M: [inaudible]

[Panel]: I think advertisers will pay big dollars for basically real-time, on-line demographic information about the information about that person who bought the white gloves.

M: [inaudible]

[Timothy Duncan]: Why don't let Emily finish up, and then we can introduce the question.

Emily Green: I agree with you, I think that "target market" may be the short way to encapsulate what you were saying. The opportunity is to really make a rightful shot to your prospect and understand exactly what they want, build that relationship, cultivate it and focus on trying to understand their specific interest. "I'm never going to buy power tools on the Internet, so don't bother me with it," you know. And zero in. There are a lot of people that are working on that, [E-shop], the company that's developing shopping software, has developed a technique that lets the server and the browser software talk to each other about the shopper's habits in the on-line space, allowing the server to customize the shopping experience even better each time.

So if I go into Tower Records and I never go into the Country and Western music space they can arrive at the conclusion I'm not going to be interested in the Country and Western promotional opportunity, but I might be interested in a jazz promo because I tend to spend my time in the jazz space. So customizing the shopping experience is a value to the customer if it's done well. That's one of the big opportunities, I agree. I'll pay you later.

Okay, so the forecast, the all important prediction. In 1994 and 1995 we size this market as — '94 I think we came out and we can identify about 240 million dollars. I'm going to

tell you what that is, that's retail sales, that's the value of the product, and we tried to total that up.

Now, it's a bit of a "chicken and egg" problem in doing these forecasts, which you may or may not know. You call up somebody like America Online and say "I'm not going to print your number individually, I'm going to sum it with everybody else's number, but I'd like you to tell me how much your merchants sold to your network." And they say "Yeah, right." And you do that with Prodigy and CompuServe and you really work it and you get some data in and you start putting that together, and then of course they come back and say, "You know, your numbers are all wrong." Of course, your industry projections are just no good anyway, so take it with a grain of salt.

But about 250 million in 1994, and in '95 we estimate about 350 million, but we see the years of '96 and '97 being a real growth opportunity. This is the famous hockey stick curve, of course. All projections have to have a hockey stick curve, I think, right? And that's because what we see happening in '96 and '97 is sorting out a lot of the security issues; it's really not impacting the consumer use, but it's really slowing down merchant and bank use of the Internet as a transaction place.

So a lot of security stuff is being settled and we're also fixing that demographic issue over the next couple of years, getting a broader penetration, and we're also seeing bandwidth to the users increase. Question over here?

M: [inaudible]

Emily Green: Yeah, I'll just give that a one sentence answer. The question was, what's the role of electronic cash in this space? I'm just going to give that a one line answer. I think consumers are very reluctant to experiment with anything that's really weird and they only want to move into things gradually, one step at a time, and the most familiar way to buy things right now is the credit card. I really think in the next couple of years that the mass market opportunity — for those of us that aren't going to take the time to understand electronic cash, the mass market opportunity is making credit card transactions safe. So I don't really think e-cash is going to play a big role in the consumer retail market. So that's that. All right, that's my last slide. I don't believe it.

Here is a summary slide — not the best summary slide I've ever done — but the on-line market is definitely growing and it has lots of growth ahead, it's definitely starting to balance, and the kinds of people you can reach will be a broader sample of the overall population. But again, it's far from ubiquitous and it's a long way from getting to be ubiquitous and it may never be ubiquitous. There is a lot of experimentation ahead, there is going to be lots and lots of attempts to create new content, create new business models. We think that most of them, probably just because of the way things look, most of them will fail, but some of them will work and there is plenty of opportunity to make money ahead. Okay.

[Panel]: I have a question. Earlier we saw some slides on revenue splits for content providers. Do you think that that's going to continue, that the content providers and the pipeline providers will be sharing more revenue?

Emily Green: No, I don't think — well, here is what I think. The question was: How does the split shape up ahead between revenue for the content providers and revenue for, say, on-line services, right? I think that over time there will be less free content as more people decide that they want to stop experimenting and they want to charge.

I think that the on-line services will trim the amount of content they have as they start looking more like a value-added Internet service provider, whereas at your pass at the Internet, on your way there you use some interesting stuff that can frame your experience of the Internet. So they'll trim their content, they'll choose it more carefully. And that may mean for the ones that are last they might pay more money, but for the vast majority the opportunity for revenue is diminished.

[Panel]: Thank you, Emily. We've got one more speaker, about 15 minutes, then we'll take questions for everybody. Our final speaker, and certainly one of our best, is John Hession. He is a partner in the Boston Law firm of Testa, Hurwitz and Thibault. Testa Hurwitz is a nationally recognized law firm known for representation of venture capital funds in emerging growth companies. John's practice includes the representation of venture capital funds and high-tech emerging growth companies, principally in the software and biotech areas.

Before going to law school, interestingly enough, John was a sales representative with [Educes Corporation], and given that and the fact that he is a lawyer you probably want to be around him [when] he dies, but...

John Hession: Given the fact that this is Halloween I'm not sure that this is necessarily a treat for you at the end of the day, and I promise this is not a trick; but I'll try to pull the fishhook out in about 15 minutes so I can get you out of here..

My comments are really a follow-up on to some the things that Oliver Curme of Battery Ventures talked about earlier, and it's more of the nuts and bolts of the financing for an Internet company. It's a little of how financing is structured. Oddly enough, it's very similar these days to what the biotech industry looked like in its infancy, I'd say in the late '70s, early '80s, with a couple of variations.

The change, if you will, from that model is that more and more you are seeing more than one partner, whereas biotech companies in the early 80s perhaps hitched their fortunes investing into one pharmaceutical company. You often see now — and it's a follow up on some of Peter's remarks earlier — that a lot of companies nowadays have several strategic partners in order to maintain their independence and maintain their options, as well as financing sources with deep pockets, all of them venture capitalists.

The thing you have to remember is that most of my comments here are going to be directed towards venture capital financing and what that looks like with a strategic partner involved. The thing you have to remember about venture capital financing...

I want to get a sample of my audience. How many are on the money side, on the financing side, if I can have a show of hands? Looking for investment opportunities? They keep their hands a little low because they don't want too many business cards at the end of the day. How many are on the entrepreneur side, or technical side, considering starting a business or looking to raise money from doctors, dentists and lawyers? Let's have a show of hands. They're actually not referred to as DDL; they're the three Fs — friends, families, and fools, not necessarily in that order.

Well, we start with the end, because that's probably the most interesting, that's the closing for Netscape. They just celebrated probably 300% compounded growth rate in a day and a half on their market cap, and the market is growing just as fast. The interesting comment on that is that there is enormous opportunity; the market is totally fragmented and there are very few bets on who is going to be the next Netscape, and as a consequence there is plenty of financing opportunities and plenty valuation opportunities. If you just look at it nowadays, it's kind of like the Winchester disk drive industry in 1983. Everybody has to have one of these companies in their portfolio.

Valuations are often in the private side and are reflective of valuations on the public side. They track each other in many respects. You have enormously robust, healthy, feverish valuations in the public marketplace, particularly for Internet or Internet-related companies, particularly those who have a leading product that have an enormous market power or the ability to leverage market share very quickly. You often see a reflection on that on the private company side.

I want to talk principally about deal terms and specifics today, what to look out for if you're an entrepreneur. Are you considering financing from a venture capital source? They are, as Oliver Curme reported to you earlier today, a strategic weapon. Some of my remarks here are to make you fire your weapon in the right direction, and not at you forehead.

Okay, deal terms and structure. Conventional deal terms for most of these financing is preferred stock. Most of the companies are C-corporations, and their earnings and their losses are captive in the companies. And you want to have the ability, if you finance that, that you keep those losses to offset against future income. But what does preferred stock do for you? It gives you enormous structural flexibility right now, [inaudible] at the limited liability. You may have heard a lot of stuff about that. It may be an opportunity to do something in the future, but people are not very familiar with it yet.

You typically have a preferred stock and it gives you a lot of flexibility; it gives the investor the opportunity to change the internal rate of return depending on how you structure the investment, and it's actually, believe it or not, despite all the bells and whistles about up-side protection or down-side protection and up-side guarantee for people, for the entrepreneur it allows you to price stock and set up stock options and restricted stock for your employees that are very cheaply priced relative to the venture investment.

What do they typically involve? Most venture capitalists do this for a living and they touch this stuff all day long, they know exactly what this is. These are the things that basically influence your investment return. It's about fifty pounds of paper, and all of this determines when they get out, how they get out and who gets out first.

You have to remember a few things here. Why is this important to them? It's important because the industry is characterized by investment funds that have limited shelf life. It's just a common phenomenon to the venture capital industry. Most venture capital funds are organized so that there are limited partnerships that die in ten years. They implode; they must distribute at the end of ten years whatever they have in their portfolio to their investors. They can't be hanging on to the restricted securities of a private company.

So they only have two options at the end of the game: the company either has to go public, and that's dependent on the market and market conditions, and an underwriter; or they have to sell the company to somebody, because ultimately they're in the game of liquidity. They have to harvest the investment in ten years. They have pressure themselves underneath them, in the investor base, to basically distribute, cash, or stock back.

So you have a number of things here in that deal structure that influence that liquidity pressure for a private investor.

Liquidation preferences — very quickly, you just get your money back. You put a million dollars in, at the end of the day you get a million dollars back before management sees the first nickel.

Cumulative dividends; we'll touch upon these briefly in more slides. There is a time charge on money. Why? Well, because I could have taken this and put it in treasury bills and made 7%. I'm not in here for 7%, however, at the end of the day. I expect to get: 1) my money back and 2) a time charge on that money, even though there is no expectation that dividend will ever be paid currently, because most of these companies do not have P&L statements or

balance sheets that can support payments of dividends, even when they go public. Why? The earnings are plowed back in to support future growth.

However, the dividend is basically a ticking time bomb. At the end of the day, if there is an acquisition it influences the rate of return, because if you have a 10% dividend, if you have a million dollar investment and it's a simple dividend, in five years if there is an acquisition, the investor gets the million dollars back plus the dividend, the \$500,000 dollars that's kind of earning but sitting out there, before management sees a nickel.

A Participating/Preferred. This is probably the most onerous of the terms, and it's actually — it looks harmless on paper; you get your dollars back plus you participate in any up-side in the company. If there is a sale of the company, it dies typically on a public offering.

Let's take a look at some of the things you will negotiate.

Management shares. Oliver made the reference that venture capitalists typically take somewhere between, I think he said 10% and 20%, 10% and 30%. That's only in the first round of investment, and there is usually several rounds of investment. The typical mix that you see before a company is taken public is often that the founder team has about maybe 30% employees that you need to attract with paper, with equity, because these people are working on a nuts and berries diet, so the reward is basically in the equity. You'll often see a reservation of setting aside a pool of capital of equity for members of the management team that you have to attract to the enterprise to grow the enterprise — technical people, sales people, marketing people each get a sliver of the stock options, because that's the promise, that's the reward at the end of the rainbow. And then the investors typically will hold the balance.

If I converted my stock or I take dollars out, I'm going to have a huge appetite for capital because it needs a very heavy marketing budget and a very heavy advertising budget, and that means a lot of dollars and successive rounds of financing.

Most entrepreneurs in this business underestimate the amount of dollars required to build a business of sustainable scale. That's why venture capitalists are there. If you want to grow a very quick business in a very short period of time, that's the kind of financing strategy you need to pursue, but it also consumes a lot of capital. A lot of capital.

Things you need to consider. Non-competition and non-solicitation agreements are common. They are not going to invest in a situation and watch key technical people, key strategic people, members of the management team decide to take a walk and set up shop across the street. They want to make sure the intellectual property is protected, so you'll see — except in California, where they are outlawed in the employment contract, not if you sell a business, but in the initial employment context they're outlawed — you will see as a condition to the closing that all key members of the team sign up one to two year non-competition agreements. This is the price of admission. It's very standard.

Employment agreements and severance agreements. If you are signing up for non-competition agreement, you want to think about — look, if you don't like the color of my suit, if in six months or twelve months from now there is a corporate divorce and we just decide to part ways, maybe you should have a severance arrangement. Industry standards are typically 6 to 12 months, depending on what strata you are, at what level you are. Six months would be at a director, your director of engineering level or VP of engineering level; the CEO might get 12 months, that's kind of customary, but again you're bargaining for that in connection with a non-competition.

One of the more painful things is vesting of stock. You know, you started this business, you mortgaged your home, it's been five people and a dog in somebody's house writing software source codes for the last two and half years, you paid a penny a share for your stock, you own it all and you're getting 3 million dollars from the venture capitalist and he says — or she says — “Guess what? That stock is going back into the pot, you didn't really earn it all, you

got it very cheap.” I don’t mean cheap; I don’t discredit the value of those services. However, if you leave in three years they need to replace that equity, they need to replace that person with equity.

If the CEO, who is founder of, let’s say, “The Enterprise,” has 10-15% of the company and decided after three years, “This is it, I’ve had it, this is too frustrating, you know it’s another 2 or 3 years of hard work, I want to go do something else,” everyone else in the enterprise, and particularly the financing source, needs to get that equity back to attract that next CEO, because there is the value in the end-game — the equity. So that’s one of the most painful things, and if it’s not on the table on day one it often becomes an impediment to the transaction at the end, if it’s brought up at the end. And that’s buying back — at a very good price — the entrepreneur’s stock, if the entrepreneur takes a walk.

There are often co-sales and rights to first refusal if management want to sell out or sell to somebody other than transferring to children or to a trust, that prior to everyone else getting liquidity they want to keep control inside the enterprise by buying back that stock and keeping it in the enterprise. Typically the company would have a right to first refusal first, followed by the investors, but typically no one else. What you often negotiate is the rest of the founder team gets a third right or shares in the second right to buy back stock if anybody else should leave. This is all premised by the idea that everyone’s got the up-side, and at that point there is a liquid trading market, that the investor, the venture capital investor has what he needs, the trading market to distribute securities to his limited partners, and the entrepreneurs sort of reach the goal that was promised in the first place.

Okay, let’s take a look at it briefly in more depth, just to consider what to look for. There is a lot of stuff I won’t bore you with. More wind is wasted over registration rights, which is the ability to force the company to go public... The key person is not seated at the table when that discussion is held, and that’s the underwriter. He is not there, he is not part of the discussion and there are twenty pages of legal “goo” that’s written about this stuff that frankly is just immaterial, so don’t waste a lot of time negotiating it. Give them what they want in registration rights; they are never exercised, and when they are it’s usually a liquid market trading anyhow. It’s a lot of words wasted over that.

There is often, as I said, preemptive rights, the ability play a part in additional financing of the company. If I’m a first round venture capital investor and I got 10% of the company and you have a strategic partner coming in, say NYNEX Information Resources, and they are buying 20% of the company, I want to make sure vis-a-vis that I’m protecting my position, that my stake is not diluted, even though I may be paying a higher price.

A couple of things. Liquidation preferences; I just want to focus on a few of these that are often opposite of the key terms on what happens. That’s basically where you get your dollars back, and the real economic affecting this is, what happens in the event of an acquisition? Does management and the investors come out side by side in the acquisition, or do the investors come first? Usually the investors come first, their dollars come before management. The issue is, do founders get a preference too? Do they get a return on their investment, too? They’re usually just holding common stock, penny-par value, that’s what they paid for it on that one. However, a lot of people have loaned money to the company, have mortgaged their homes to get things started, and one of the things you ought to consider as an entrepreneur is whether or not you share in a liquidation preference, because you put hard-earned dollars into the enterprise. That’s an important part of the discussion.

Participating/Preferred. This is probably the single most dramatic clause; it’s a sentence and a half in the fifty pounds of paper that you get and it alters the landscape dramatically, depending on what the liquidity event is. Participating/Preferred basically says I get my dollars. Let’s say I made an investment in a company for a million dollars and I bought half of the

company on day one, and the company was sold three to four years down the road for four million dollars. What the participating/preferred says is: if I own half of the company because I put a million dollars in, okay, I get the million dollars back first, and then based on what my conversion rate is on the preferred — and remember I said for a million dollars I bought half the company, no further financing — so I get my million dollars back in the 4 million dollar acquisition, that leaves three million dollars left to be divided up.

Half of that 3 million dollars, or a million and a half, goes to the venture capitalists. This is usually a very common structure in an early-stage financing, particularly for an Internet company where there is an enormous amount of risk. You just don't know what it's going to look like in a few years, and if there is anything that eats into management's hide at the end of the day, if there is an acquisition, it's that clause because that takes a lot of dollars off the table. Usually what people negotiate is called "IRR hurdle," that is if we do an acquisition at a fairly decent valuation and you get, let's say a 30% compounded annual rate of return, this thing automatically dies.

But this is a very tough clause. It's innocuous-looking, and most entrepreneurs don't know what it means until they start doing math, and I guess what I would do is when you see a clause like this, start doing math. There is a question of basically what the investor gets in the principal back and recovers in the up-side.

Cash-out elections. This hurts your flexibility in the future. What is a cash-out election? It basically says that if the company is sold, if there is an acquisition of the company, then I have the ability to decide about whether I get what I would receive if I converted my stock, or I take dollars out of the company. The unfortunate part of the problem, and this is where you need to almost work with your accountants on this in the early stages, is that most financing of the Internet companies, if you look at it, there is going to be a wave of consolidations and acquisitions in the next three, four or five years. And this frustrates what's called a "pooling transaction," the ability without any deleterious accounting effects to merge balance sheets and P&L of two companies as if they were existing on day one.

For example the Microsoft-Quicken proposed transaction. It was structured as a pooling transaction, and what is that? I swap stock for the target company's stock, and we merge balance sheets and P&L. And what does that mean? It means historically it looks like we were joined at the hip from day one, and all that happens is that Quicken's earnings or Intuit's earnings run right into Microsoft's P&L statement and their balance sheet, their earning statement, as if they existed from day one.

A cash-out election... When you consider that in most acquisitions structured for software companies, our preferred mode is a pooling transaction where people do a tax-free stock swap. And this kills it because if you have the ability to take cash out of the enterprise, it hurts a pooling. So the thing you have to remember is that if you do a financing that has this cash-out election clause — and this is the jargon you will see in term sheet — it really hurts you downstream if you're going to do a pooling transaction. It makes the company less valuable. You're negotiating at the table not only with the potential buyer of your company but with your investor right behind you, and you have a lot of flexibility. Question?

M: [inaudible]

John Hession: That's my point. Usually a stock swap is cash, is tax-free, and you only recognize the tax when you sell the underlying shares. For example, in the Microsoft situation Microsoft gives shares to Intuit for — you know, the Quicken product line — in that when the Quicken holders sell that stock, and you can time that whenever feel like it, when you sell that stock then you get whacked with a tax. What this does is make the transaction convertible from a

tax-free transaction. And from an accounting prospective, if you're paying a premium over book value, all of that difference between the value you're paying for the company and what the book value of the company is is a charge to earning for the buyer. Buyers just don't like that; they will pay less for companies on valuation if they have to take a charge for earning. It's neutral if it's a tax transaction. It really influences what happens to your future in many respects.

Cumulative dividends. We talked about it, and there is no exception of payments, it's just — remember what we've got here. I want my money back, 1 million dollars and 10% interest in essence, but it's not currently paid. It's usually forfeited if there is a public offer. However, in an acquisition that's where it's recovered, and that can influence rate of return. If you did an acquisition five years out, and you had a 10% dividend on a million investment, that million dollars of liquidation preference is now worth a million and a half dollars. It grows slowly over time but it has kind of a compounding effect. Question?

M: [inaudible]

John Hession: Absolutely, annual...

M: [inaudible]

John Hession: Yeah, there are a lot of laws in most states that say that Visa card companies can't charge 18%. But that's what this is. But you will see that there is not expectation of payment; only if there is an acquisition of the company. And you don't get out at a predetermined rate of return.

So yes, you will see — and where is it appropriate to see it is in a very early stage of financing that the management team has not fully developed the business plan or marketing plan, and may not be quite launched yet, and the product is just coming out of prototype. There's a lot of risk, and therefore that rate of return of the 30% built-in rate of return is sort a natural for that situation.

[Tape change]

John Hession: ...is painful, that's where it's very painful. And the earlier the stage of financing, the more you will see that. Strategic partners technically don't ask for these kinds of investment vehicles. However, they're getting smarter, and they are basically saying, "Well you know if you have the first round of financing with Battery Ventures, and we're going to make X," you know NYNEX comes in and says, "We're going to do an arrangement where we provide you service, the ability to be one our long distance network or use some of our services as well as make a strategic investment, because it makes the company look good," you've got a partner that's validated the strategy.

What often will happen, and this is in very difficult negotiations, is that investor will say: "Well, we'll just take the terms as your first round investor." If you're a first round investor your venture capital investor has tough terms, and it's going to get doubly tough, because now you have a strategic partner who is looking for the same financial rate of return that the pure capital investor is looking for, and he is getting more in the transaction; he is not just taking money or giving money, he's providing services, and he is maybe getting content or services or technology from you.

You know, you raise a good question, and it creates a lot of problems because as I said, a lot of the models nowadays have both the financing vehicle, the pure financing vehicle, the venture capitalist with a great Rolodex and good contacts for strategic partners, and a strategic

partner who has several directors. It's got a financial directive, it's got a technology directive and it's got a distribution directive. And sometimes it's hard to marry the financing model with those directives.

Okay, anti-dilution protection. This is if you sold a valuation at this price, and you go out and raise the money below for foreseeable future. For example, we value the company — before the venture guys come in — at 5 million dollars, and it translates to \$2 a share; this basically says I have the ability to re-price my investment if you do a financing below that \$2 per share valuation. If things get tough, you're behind in the marketing plan, you're behind on the technology and development curve and you're not going to make payroll in two weeks and you don't have a plan of financing and you need about a half million dollars of bridge investment, that's when this terminology comes home to haunt you. Because if you've got to raise money at a cheap price, the investor gets a second look and has the ability to re-value the investment at tomorrow's lower valuation. If your valuation goes up, it's ignored.

You know, everyone has made the right bet, and the value is going up. If the valuation goes down that investor needs to participate in the company, to support the company. Let's say now I'm coming back in and I'm investing at 50¢ a share valuation rather than \$2 a share valuation; that earlier valuation gets re-priced. And the effect of that is that the earlier round investment gets more shares in the company as a consequence.

What can you do to ameliorate that effect? Well, you can have things like if after a certain period of time it expires, after you get an investment from a strategic partner and it expires, you can do any number of things, and I always say look at the economics of the situation, and look at the where your cost-to-capital is going to carry you.

If you have a two year cost-to-capital that these finances are going to support you, then maybe it's natural to protect the investor for the first two years where there is an extra risk that you may have to go out and raise more money at a cheaper; but thereafter everybody is in the same boat at that point in the game when we all should share the risk on an equal basis.

Here is a key thing that you have to have and that you need to negotiate up-front: a "basket" for management and employees. Typically you'll see that both management and investors recognize that while technology may drive the situation, it's people more than anything else that make the enterprise very successful. You need to attract people to the enterprise, and to do that you need to give them some equity, and you should regard your equity quite jealously. You should not give it away like candy. There is a lot of companies I see do it; they like to say that everybody gets an option in the company, from secretary all the way up.

Well, I have a feeling that secretaries, when they get a five to ten page option agreement, really don't appreciate or understand or care what this is, and the numbers are meaningless to them. I think it's more important that you have an option program that rewards people for contribution to the enterprise, because this is where people have the possibility for becoming millionaires three, four or five years down the road.

You should also realize that attrition is high in this industry, and therefore you should tie your option-vesting schedules to ones that make sense. You should have any portion of the option become exercisable or vested, so the employee has a right to touch it and exercise it in the first 6 to 12 months. Why?

Attrition rates in this industry are the highest in that period of time. Why give somebody equity who can walk away with it when there is a possibility you never got what you bargained for, which is maybe a two, three or four year commitment? And you should understand the commitment level required. Are you two years away from a public offering or four years away from a public offering? If you're four years away from a public offering or an acquisition then you should have a vesting schedule that may be dependent on those four years

that the stock — that's over time at 25% annually — so the linear performance of the employees is tied the economic model.

We think we are going to get there on the curve, on Emily's hockey stick, at the top of the curve in four years. Have your option program tie to that performance schedule. Why? You don't want to run the risk that you make a lot of people millionaires too early, and then they — you know, the beach in Tahiti looks a lot more pleasurable than the streets of Cambridge.

You know, I had a classic situation for a company that we just took public about three months ago, and they put in an option program about a year and half before they went public. All the top management got to sell their shares and their options in the public offering, and the VP of Sales said "Oh, I've been doing this for eight years, and eight years is long enough, I feel like doing something else."

And six months after the lock-up expired, he sold his shares and gave his resignation. You know, he was tired, but the problem is that you didn't get the reward out of that you were looking for. So tie your vesting schedules to your horizon for what you want this company to be. And not longer than four years, because longer than four years is an infinity.

Okay, there are a couple of things about the investor wanting his money back, and usually if there is a [port] right, there is the ability. And why is that? Investors have liquidity concerns and if they have to get out of their investment in five or six years this is a way to get out of their investment — they force the company to buy it back. I sort of say "Good luck" to the company that doesn't have any money and is bound to something that they can't pay for. You're squeezing blood from a stone at that point. These sorts of clauses, I think, are worthless and there are a lot of fights that go on over it; but at the end of the day, to me market success is the best indicator of the economic performance. If the company is doing well, this thing disappears.

Board composition. This is important. There is a lot of political and emotional and personal issues that go into this kind of mix. How is it determined who is going to be on the board? And my suggestion is that you really don't want a board of directors of more than five people. Seven or eight people, it's like Caligula — it's a Roman orgy, and you never get anything done, there is a lot of paralysis in decision-making, there is a lot of people expressing opinions. It's better to take a position, understand it, make sure it's fully supported and head in that direction rather than have five different voices suggesting where the company should go.

You all should have what I would call the "martini" rule about venture capital investors on the board. I think management, the proper board mix may be one, possibly two people from management, typically the CEO, maybe the VP of Sales, VP of Marketing. And as the company grows, that drops off, because what's a board supposed to do? The board's main role is strategy and direction. They should be giving you guidance as to where the company should be going, giving you feedback not on day-to-day tactics, [but] on is this the right choice, is this the right direction, is this the right partner to be with, is this the right structure for that partner? So you should look for people typically who have industry experience, either operational experience or sales and marketing experience. I said to you those three things are key ingredients, someone with outside industry experience in the sales and marketing side.

Because this is usually where there is a critical failure, a critical lack of talent in the early stages. And what you should also have is maybe one or two investors. But what I usually advise against is the martini rule — having three venture capitalists on the board is kind of like having three martinis. The first one you're feeling relaxed and comfortable, the second one on the board you're feeling very, kind of heavy a little bit, but the third one is a guaranteed headache in the morning. So limit those.

Voting Agreements. Voting agreements are basically how you structure the board so you are guaranteed an input. Okay, couple of things; this is the last slide, I think, so the fishhook is out and it's kind of coming on my neck from Tim.

A couple of things to think about, as I said. A lot of the financing models nowadays have a professional investor in it, a venture capitalist as well as one or more strategic partners. And that's key. The biotech model usually had one and that was part of the problem; you hitched your faith to a large elephant that you didn't know what direction they going in, and the problem was you often got stomped in the living room.

Venture capital and strategic partners. By that I mean people who work and leverage your resources: on-line services, large software companies with multi-faceted distribution channels, whatever. By venture capital I mean someone who is providing directly. For venture capital there is a very large impact on management economy because they are on your board and they are reviewing your situation on a month-to-month basis. For a strategic partnership, depending on whether or not you got an exclusive arrangement or several non-exclusives — and the later is a low impact on management autonomy, except for the early stages when you have to build the program. There is a lot of time that kind of goes into it, six months to nine months of building a strategic alliance, and that's getting and selling people on the market strategy and the distribution strategy. The balance of that, really, is making the thing successful, and that's usually people just below who are heavily involved.

In terms of management involvement, venture capital is a very high involvement on an ongoing basis, because they have to report to their limited [partners], they have a number of portfolio companies they have to manage, and the goal is liquidity at some point in the game so they have to make sure this company is on the right track, it's hitting all the right milestones in terms of the product performance, in terms of signing up other partners, in terms of revenue ramp and distribution ramp.

For strategic partnerships and management involvement in the implementation, it's often a very high time commitment. Progress reports, meetings, that sort of thing, a lot of tactical issues that are dealt with.

The ongoing involvement really depends on whether or not it's an exclusive partner or several non-exclusive arrangements. You know, as Peter was saying here earlier, I really would recommend that you really have to consider non-exclusive arrangements if you want to be successful, and make sure you maintain you independence.

We'll go to the next one, and there it is. We started at the end of the process, the Netscape public offering. And you know, hopefully that's exactly what you have to do at the end of the game here. You've got a successful venture capital investor, several successful strategic partners, and now it's time to consider a public offering. That maybe reversed; that may be looking for venture capital investment, and there is kind of a "pig on a poke" maybe sometimes, but it's a little bit about what this process is.

It takes — you have to remember this is a long process and there is a lot of luck in it. A lot of entry firms like Battery Ventures, for example, whom we represent... You know, a partner in a firm like that might get, on average, 400 business plans a year. Oliver Curme might do three to four new investments a year, because he's also got to manage existing investments. So that's [inaudible], to get from 400 to four is enormous.

And a lot of times it's luck, it's having what I believe is a great executive summary. It's what Emily and I were talking about in the break, the 30-second elevator ride where you can tell your story and you can understand the market opportunity in basically a flight through ten floors on an elevator.

So, with that, good luck going on up on your elevator. I wish you well. Make plenty of money because the rising tide lifts all boats.

Timothy Duncan: We've covered a lot of real estate today. It was a long afternoon, we got some great speakers, and I hope everybody got some information from the program. I'm in the book and there is a speakers guide. If anybody would like to make any comments, my phone number, address, and e-mail address are all in there and we are probably going to do something like that in the Spring, so if you have any comments or suggestions, please feel free to give them to me.

Thanks a lot.

ACCESS PROVIDERS

SO YOU WANT TO BE AN ACCESS PROVIDER? HERE'S HOW!

SPEAKER

Bob Berger

Chief Technical Officer, InterNex*Tiara

Bob Berger: I'm Bob Berger from InterNex. To become an Internet access provider looks easy from the outside. When I first started, I didn't really have an intention to be an Internet access provider; this was in early 1993, and my goal was to really start offering services to help people access and utilize the Web, which was really new at that point. At that time I had done some work previously with ISDN, and I expected all the Internet service providers to be rushing out with ISDN access to the Internet, because at that point the only choice you had was analog dial-up or T-1s. Analog dial-up, I believe, is too slow for actually utilizing the Web, with graphics and audio and things like that; and T-1 is too expensive for most businesses to really use if they just want to surf the Web and access it. When I called around to all the existing Internet service providers, I found no one even had any plans to do ISDN, so I thought, "it can't be that hard..." So I found out it's really hard.

When you're going to start up being an Internet access provider the first thing you have to decide is what kind of scale of operation you want to aim for. It can be anything from a small, single POP — really just a step up from a hobby — where you want to just service your town or your city; you're in a smaller area, so a single POP potentially could service a town or a small city.

The next step up would be a regional operation, where you're going to cover an entire region like the Bay Area or the west of the Boston metropolitan area, or something like that.

And then finally there's the big leagues, there's the multi-regional, where you might cover several states or national. So you really should decide that in the beginning where you are going to target.

The next — just as a side thing, a POP is a "point of presence;" it's sort of the atomic element of any kind of Internet architecture. What's important about POPs is that's what creates your local point of presence so that people could have local dial-up access; if you don't have local dial-up, then that means that besides whatever fees you're charging, the customer will also have to pay any long-distance charges — and most customers are not willing to pay a long-distance charge if they can get competitive service without it. In some areas people are using Centrex as a technique to give flat-rate calling to their customers. I believe that Centrex coverage is an artificial loophole in the phone tariffs, and will go away as a technique for giving people flat-rate access; we'll talk a little more about that later.

So if you are going to go after the idea of doing a single POP for a small location, that's the least costly approach, and it doesn't have that many challenges. You can kind of do it with just a little bit of hardware; it costs about a little more than a car to set up. But I believe that you won't stay alive very long; if it's just a hobby and you really don't intend to make money you'll be fine, but it has no long-term viability.

[Being a] regional provider takes a lot more work. We are located in the Bay Area, which is one of the most competitive Internet access markets, and it took us actually about thirteen POPs to cover the Bay Area; if we were to use Centrex we would have had to put in many more. A regular POP covers about twelve miles, and that's really dependent on the tariffs in your area; but with most U.S. RBOCs it's about a twelve-mile radius in metropolitan areas. If you did Centrex, Centrex has about a three-mile coverage; it's really what can connect, usually to the central office, that the Centrex block is on.

Doing a regional business is technically and financially much more challenging. You're now talking about easily hundreds of thousands, if not millions, of dollars. Also the technology to deploy it — it might look simple, "oh, you just need a bunch of servers and a bunch of dial-up ports," — but to do it right, to do it with quality, as we'll go into, takes a lot more. And you're now into a big business; you have to have all the things a big business has. You have to have strong sales, strong marketing, financial operations, inventory management, and capital management. But I think that there is still a niche, particularly in a lot of, not the top cities, but in a lot of the secondary cities' it's going to be a while before the big people have coverage into those areas, so I think this is a potentially viable marketplace still. But you have to expect that if you stay a regional, eventually there's going to be a consolidation and you'll either be bought out or put out of business, one or the other.

And then finally there is the multi-regional providers. That becomes even more difficult technically, because now you have to worry about interLATA communications where you have to utilize carriers that can cross boundaries; you can no longer use your RBOC's frame relay clouds. You have to find providers that can backbone all your traffic across regions, across state boundaries, and across LATA boundaries. Your routing and network management become much more difficult, and the capital at this level starts to become — we're talking the UUNets and PSIs and RBOCs — which are capitalized, as we'll talk about later, at 40 to 100 million, or billions. And the sales and marketing efforts become even more tough.

So once you decide what kind of service area or scale of business you want to do, then you have to decide what type of Internet service you're going to offer. At the low end there's the analog dial-up using shell accounts. There is dial-up PPP direct connections, high-speed ISDN, and then dedicated services.

The shell accounts are what a lot of the older companies started with; NETCOM really started as a shell account company. It's the easiest way to get started [because] it doesn't require a lot of routing experience. It is really a UNIX kind of operation, but it requires a lot of UNIX experience; you're going to basically be a big UNIX system administrator.

The other downside of it is that it doesn't scale well. Once you start getting up to the thousands of customers, or tens of thousands, you're hitting some boundaries of UNIX time-sharing and it doesn't allow you to — you can't just throw machines in to get bigger. You have to really start re-architecting, and you just hit some brick walls. I believe that's why with the performance of a lot of these systems, like NETCOM, it's not their networking that is congested, it's their servers. And it doesn't support client/server applications very well; you really can't run *Netscape* from a shell.

The next interesting area is still using analog dial-up, but using PPP or SLIP as the connection technology so that your customers will then connect to you as a direct IP connection. That means that their computer, when they're connected, is connected directly to the Internet and they can fully utilize all the client/server facilities like *Netscape*, FTP, things like that. It is still modem-based, but your speeds are in the low end; it's 14.4 to 28.8 modem speeds. And also for the customer, for them to connect to your network takes twenty seconds to a minute and a half every time they want to connect — and that doesn't allow for creating a virtual link.

What we have specialized in is ISDN access. I believe that ISDN has a pretty good future at this point, at least for the next couple years. It stands for "integrated services digital network," but people always made up silly acronyms for it. It used to be "I still don't know," but now the RBOCs are saying "I see dollars now," and Bob Metcalfe coined his "info superhighway delivered now."

The biggest thing about ISDN is obviously the fact that it's about ten times faster than a 14.4 modem; that alone is enough to make it interesting. Once you cross over the 56K speed

boundary you can do things that you normally wouldn't do. Using the Web actually becomes a productive tool; you can really use it as an — you just basically have it on your desk all the time, and you click on things when you want to find it, and you're not sitting there waiting for the graphic to just come down for a minute. It really changes the whole way you can utilize the Web. And because of that speed, it also allows you to use it for LAN connections, so it's suitable for connecting small LANs for businesses to the Internet.

In the last two years there's a lot more hardware now available to connect ISDN to Internet services. On the show floor there's Ascend, which is making some of the premier equipment. And what used to be CombiNet, now part of Cisco, also makes some excellent products. And there are now products in the under \$400 price point to connect PCs to ISDN; so that's a kind of an enabling technology.

We have a couple more things... There are some subtle parts of ISDN; the fact is a call can be connected and completely set up, so that from the time you start the call to when you're routing packets can be in the order of a second. That again creates a new paradigm of how you use dial-up services; the fact that you can have a call set up in a second means that you can have your line go up and down on the order of every couple minutes. So let's say you click on a Web page; you're now reading that page and it might take you a while to browse through it. The line could go down while you're reading, and as soon as you click on another link the router senses that you're trying to route some packets and will bring the line up in a time that is imperceptible to you.

For an Internet service provider that's great, because that means that your dial-up ports are going to be able to be utilized much greater and by many more customers. And for the customer it's an advantage because even though it feels like they're on-line five hours a day, their actual connect time would only be a couple hours. So that's really a key feature that people don't really know much about.

Now, as I said, the graphics are much more accessible [using ISDN]. Using the Web is much more accessible; telecommuting becomes much more of a reality. As an Internet service provider telecommuting is one of your secondary businesses; if you are putting out these POPs you can sell the access of those POPs to corporations that want to aggregate their telecommuting traffic through your backbone. With ISDN you can do a lot more kinds of file-sharing and kinds of telecommuting type of work, so it really makes the Internet a much more serious business solution. With modems you can toy with the Internet, but to really use it in business you need the speed.

Finally there's high-speed dedicated services. These require much more technical sophistication but are also much more lucrative, and they also help you create your backbone. Today the key ones are frame relay, which is very popular now and very easily accessible; most RBOCs supply it in very low-cost forms. Point-to-point has been the traditional way that people have done high-speed connections; the downside of point-to-point is that you have to pay for the T-I between the customer and you on a per-mile basis, and even if it's just sitting there you're paying for it, whereas with frame relay SMDS they are distance-insensitive. The customer has to pay to connect to the cloud, and you just have to pay to connect to the cloud; there is no distance charge. And because of the statistical multiplexing of the cell and frame-based technologies, the costs are much lower.

So let's say you have now decided that you're going to do one of these services; you have to decide how you're going to allocate IP addresses. Most people getting started think, "Oh, well, I just get a Class B." Basically they're not giving out Class B's anymore; you have to now get chunks of Class C. They're called CIDR blocks, and this becomes a major headache both in terms of — if you're a small provider — trying to get that, [since] the Internet will no longer give that out, and then managing it. We'll talk a little more about that.

And that sort of leads into the [matter of the] feed. Once you get started, one of your biggest problems will be finding a way that you can get your fat pipe to the Internet backbone. You have to be connected to a cell. One of the things that I found a little confusing when I got started is a kind of the search for the fountainhead of the Internet. The Internet has no central authority; it has no central point that it emits from — it's a network of networks. So you still have to find some way to connect, and you need to find some way to get blocks of IP addresses that you can utilize to sell to your customers that are on your network. So I'm just going to review now kind of what I went through in trying to find that.

First you think, "well, I should just go to the InterNIC; they're supposed to be the closest thing to running the Internet." And what I found is that [InterNIC] was funded by the National Science Foundation, but it's there mainly to manage the address base and the domain names base. What's happened in the last year is the InterNIC will now only give blocks of addresses to major Internet service providers; they expect others to go to an Internet service provider to get their block of addresses. Then I thought, "well, there's the Commercial Internet Exchange." They were founded to purposely support "peering" of commercial Internet providers; part of their fundamental agreement is that they will route packets between all the members. But it turns out that a CIX membership does not give you transit — meaning that if you have a CIX membership and you buy the routing option you can route to any CIX member, but they will not route it past their customer base. So that's what "peering" is called.

What you need is a transit link, meaning someone that will take your packets and connect it to anyone that's on the Internet, even if they are not a CIX member. So the CIX can be a good thing to join because it does give you a certain kind of connectivity, but it's not the only kind you need. Then you might have heard of the NAPs, the "network access points," which is the remainder of what the National Science Foundation is funding; it's a place where national Internet service providers can peer. But it is, again, not a place where you can go and just buy a connection and be guaranteed that your packets will go anywhere.

At this point there are four NAPs. Again, it could be an interesting place to connect if you can buy transit from someone that's there; but today at most of the NAPs you need to have an ATM connection, so you have to be able to step up to being able to both technically support ATM and financially support it.

Then there is what I call kind of "the cartel," because that's what I discovered there seemed to be. There is a group of the large Internet service providers; they all agree to peer with each other, and there are actually public peering points where you can buy from MFS a connection to what's called Mae East, or Mae West, and there is now, I believe, a Mae Chicago. This is a place where Internet service providers can buy from MFS a Layer 2 interconnection that is the equivalent of Ethernet or FDDI connection; and all the packets — a friend of mine called it a dog pile — all the packets kind of go in there, and you can theoretically peer. But, again, you have to have a peering relationship with someone so that they will actually allow the packets to enter their routers and enter their networks. So again this is a place, if you have a connection, [where] you might be able to arrange a peering situation, or you might be able to buy transit from someone there and use that as a place to connect to them.

A lot of small Internet service providers go to what I call the "gray market," and that is other local service providers that happen to have a feed and have the ability to resell it. But what you have to watch out for there is that many of these providers might only have a T-I and are already radically overselling it; so you might be one of a hundred T-I's all being fed from the single T-I that they have. Plus, again, there comes the issue of who controls the IP addresses you get. If you are now getting an IP address from their provider, you are now three steps removed from controlling your IP addresses.

When I started the business, what I did was I ended up buying a connection from Sprint. At this point I believe Sprint and UUNet are the only ones that will sell you explicit T-1's that you can resell — though I have heard that Sprint might be trying to get out of that, [because] the problem is the cost. And again, they control your IP addresses. Some of the other national ones, at least when I last checked, were not selling to resellers. And then finally a new company arose about a little less than a year ago, and they so far have been kind of the champion of Internet service providers, where their business model is to sell to other providers, and they are designed to be a backbone-only company. You can probably access them on the Net at [www.\[AGIS\].net](http://www.[AGIS].net).

So let's assume you have arranged to get a connection; the next step is putting things together and figuring out what kind of equipment you need.

By the way, at anytime you can hold up your hand if anything's not clear.

So you have looked at what's available in terms of feeds; now you have to determine, based on the kind of services that you are going to offer and the kind of area, what kind of speed of feed you're going to get. And the minimum is really, I believe, a T-1, and even that's becoming a little bit low now. Yes?

M: Does [AGIS] provide your connectivity to the CIX and the NAP?

Bob Berger: They provide physical connectivity and a route through the CIX; you have to be a CIX member, but they have private peering. The question was, does [AGIS] connect you to the CIX and the NAP? [AGIS] has connections to all those points, and what you buy from them is transit. To actually peer with the CIX you would have to be a CIX member, but it is kind of a moot point because they have direct peering relationships with almost all the CIX members directly; so you basically get to everybody through an [AGIS] connection.

W: [inaudible]

Bob Berger: The question was if you are going it alone, should you still be both a CIX member and a NAP member? The CIX membership only makes sense if you are in California LATA 1, because otherwise you have to buy a long-distance SMDS connection to connect to them. In terms of being a NAP member, you don't really need to do that; that's only if you were going to be very large and be a national provider at this point.

M: One last question. If you are a small service provider, a very small service provider with shell accounts or something like that, would you recommend [AGIS] as a good way of going?

Bob Berger: The question is, if you are just doing a shell account style, would I recommend [AGIS]? At that level you have a little more choice. The Sprint connection, or [AGIS], or even the UUNet could be a good option because you don't need that much bandwidth; you're not reselling IP addresses. It's really when you start reselling IP addresses that it becomes a little more complicated. But if you're just doing shell accounts, that is really one machine, or just your machine that is connected, and the people like UUNet don't really consider that reselling.

Something that's probably even more important than having just a T-1 is — again, most of my talk from now on will be mostly focusing on PPP type situations where you're having connectivity — and in those cases it is really important to have multiple feeds, because what we found with Sprint was that Sprint for a while was our only provider, and every time they had a problem, we had a problem, meaning there could be days of down-time for all our customers.

M: I have been asked a question by a number of people. What if you're a large company with your own Internet number and you're not happy with the service providers? Can [AGIS] provide the necessary [inaudible]

Bob Berger: The question was, if you are just a direct business feed, would [AGIS] sell that? I believe so. So, getting back to having dual-homed connections, that becomes really critical for a quality service — meaning that you would have at least one T-1 from one provider and another T-1 from another provider. What that allows you to do, assuming that they are not really coming from the same source, is that when one goes down, you have a hope that your whole service won't go down, and that you will be able to reroute. Just like in case of an atomic war, you reroute the packets to your other routes.

The thing about doing multi-homed is that now you're stepping up to a much more sophisticated routing situation, and you're doing what's called "BGP routing," and we will talk about that a little bit more later. Then if you're going to do a regional kind of operation or you're going to be doing a lot of Web servers, you really have to jump up to 10-megabit feeds or greater.

In terms of location, if you are going to be a small provider, obviously one location is going to be okay. Sometimes what's probably the most important thing is where you put your backbone operation, because what you really want to do is be on fiber. You want to ideally find a place that's what we call a "fiber nexus," where a lot of different telco facilities bring their fiber to a termination point, because that gives you the ability to scale your business. It's also possible to get cheaper bandwidth that way. And if you do that — or actually wherever you put your operations — get a long-term lease. You're going to pay a lot to have lots of T-1s and fiber and equipment and custom racks and things like that put in, so you want to make sure you can stay there for a while.

The network operations center, the place where you kind of run your network, ideally should be in the same place as your backbone operations, but it doesn't really have to be. Same thing with the business operations; again, depending on your scale, you might find that you put your machines in one place because it's great fiber, but it's a terrible place for people so you might put your business operations elsewhere. That, of course, complicates communications within your company; but sometimes it works that way.

I had some difficulty trying to decide what to put in this slide, so I kind of aimed it at a middle to high range of the kind of service we provide... Again, if you are just doing a single POP or a very small operation, a lot of this could probably be compressed into one Cisco 4000; but if you are doing something that is multi-POPs, you really have to aim for this kind of architecture. You might be able to start out smaller, but when you put your architecture together think at least this scale. If you are going to have multi-homed greater than T-1 backbone connections, you need a 7000-class Cisco router because you are going to be doing BGP routing, and today on the Internet the biggest limitation is the routing tables. That's the place that is being squeezed right now; the routers can barely hold the routing tables for the entire Internet. And if you are connected to a backbone, you must be peered with that kind of scope of routing tables, so you have to think of a 7000-class router. It also becomes important if you are going to supply dedicated services.

So you can use the 7000 as the place where your T-1s for your frame relay for your customers will come in. Then, if you are going to do multiple POPs, you really have to think about your internal routing protocol. The external routing protocol is BGP, which stands for "border gateway protocol." That is probably the most esoteric of the routing protocols, and is the one where you really have to make sure you have experts in-house, or on call to help you set up and maintain it. Then internally we use OSPF, which allows us to create a pretty

sophisticated hierarchical routing architecture for all our POPs, and we use dual Cisco 4000s so that we have redundant routes when it goes down. And then all our POPs are connected to these 4000s through frame relay.

Again, this is the kind of stuff that surprises you when you get into it. There's probably not that many people in the world that really can put together these kind of networks. The kind of problems that you have are things you just can't expect, and if you're connected to the backbone it means that you potentially can screw up the backbone. You hear that the TCP/IP is supposed to be all robust, and could withstand nuclear wars and things; but it is possible for you to put a configuration into that Cisco 7000 and it will at least screw up your neighbors — and your neighbors could be MCI or Sprint or whatever. So you have to be pretty knowledgeable at that level. Then internally, if you're going to have a large internal network, again it's sophisticated routing that's kind of on the leading edge.

M: What are your recommendations on servers and what the range [inaudible]

Bob Berger: I will get into that in a minute. We show an FDDI ring as connecting all our routers and servers; that could just as easily be a high-speed Ethernet, or just regular Ethernet. Again, it depends on your scale. You could probably start off with a switched Ethernet, but if you're doing multiple T-1s, if you're doing multiple 10-megabit feeds to the backbone — which is what you need to be at if you're at the regional level — you need to have greater than Ethernet speeds in your internal backbone. And for today, we use FDDI. Maybe in another — even starting today — in another three to six months, one of the high-speed Ethernets could be an alternative, or even ATM. And of course you need to have UPSs, "uninterruptible power supplies," everywhere, or at least a central one.

So to answer your question about servers, routing is just one part of the service you have to offer; there are then a bunch of services that are considered integral to an Internet access provider. So the equipment you need, or the kind of equipment you need, are basically UNIX servers, and you want them to be reliable and robust because they are basically now mission-critical elements. You need at least two servers, and really the minimum is closer to four, because you should basically have at least a server per service. We'll talk about the services later.

You also want to be using RAID arrays for your disks for DNS, mail, and news and things like that. And of course you need backup and, again, the UPS. We'll go a little more into some of the things you do with these servers. We use Sun Sparcs running *Solaris*; there are providers using Pentiums running BSDI. I recommend not using cheapo PCs.

M: How about Macintoshes?

Bob Berger: Well, Macintoshes, they would have — the question was, how about Macintoshes? Macintoshes would have ease of use and they have a lot of facilities, but I don't think that they are adequate for this kind of operation. Again, if you are doing a smaller-scale operation it could be okay; but I think the OS's on Macs — there isn't an OS on Macs, so....

M: How many clients are you talking about on your system? You say "our" system. Approximately how many people would this be?

Bob Berger: The question was, how many people or how many lines would this kind of service support? At the scale of two to four servers, that could probably support in the order of a

thousand, maybe a little bit more. Depends how heavy of users they are, if they're modem users. About three hundred to five hundred ISDN users.

M: Simultaneously on-line?

Bob Berger: No, we're talking about an installed base, a customer base. I mean, it depends upon what kind of quality of service; the service we offer, we tend to be more a higher-end, premium service. It depends what your customers are doing, what kind of customers they are. We are in Silicon Valley; they tend to be really demanding and expect tremendous technical support.

M: [inaudible]

Bob Berger: I was about to talk about that. Again, this is a little review of the kind of software that you will be running. I think Windows NT is not quite there yet, or at least I wouldn't do it; there are some people — as a matter of fact [some] RBOCs — doing it. Microsoft is doing it. I think Microsoft is having problems because they're doing it; it's a risk and it's not worth it. I mean, I don't think that all the services, all the security issues, all the tools are there yet. Maybe in a year; I expect, unfortunately, that Windows NT will be the platform that everything is on in the future, but today I won't use it.

We talked about kind of the backbone operations, the kinds of stuff you need just to offer the services — yes?

M: Could you back up to that last slide for another moment, please?

Bob Berger: Maybe. Actually, not right now. These will be published as part of the CD-ROM, and I will try to get it on my Web page, too.

So we talked about the backbone operations, kind of like the back-end stuff. The next area, the network operation center, is basically kind of the user interface to your network operations. It is where all your people, your engineers and operators, monitor and control the network, so you will need again probably another UNIX server. We use Sparcs running *Sun Solstice*, *Sun Set Manager*; we use that to do all the network monitoring so hopefully we know about problems before our customers do. It's pretty important to have some kind of network monitoring so that you can tell if your network is having problems. In the back?

M: Please repeat the questions so we can hear them back here.

Bob Berger: Sorry. The last question was, can I repeat the slide, and I said "no."

So besides network monitoring you will also need to have some mechanism, some tools, to do customer turn-ups. Adding a customer to whatever system you're using, entering it into your billing system, that's an area; and then you need some kind of trouble ticket system. We are using the *Remedy ARS* system; it's a multi-platform system that allows you to track trouble tickets and dispatch them.

So from the backbone we now go to the "point of presence." Again, the purpose of the point of presence is to give your customers local calling so a local phone call will connect your customers' computers to your network. You have to allocate — again, we're talking about PPP or direct connections, we are not talking about shell — you need to allocate and manage IP addresses down to the POP, and then you need to have some mechanism to authenticate your users. PPP supplies the client level. It allows people to transparently log in and authenticate with a user ID and password; but then you need something on your POP that your router uses to

actually manage the database of customers. When you start getting up to hundreds and thousands of customers, that becomes an issue. And there's questions of "does it happen locally at the POP? Does it happen back at your central site?" We happen to use a distributed *Radius* database to do that. Yes?

M: What is DNS?

Bob Berger: The question is, what does DNS stand for? DNS is "domain name service." We will go a little bit more into that.

Another exciting feature of POPs is that they generate huge volumes of billing information. You need to be able to capture that and process that as well. Every time your customer calls in, it is a record; every time they hang up, it's a record.

We believe that it is important to distribute the services we talked about — mail, news, DNS, things like that — down to the POP, so that as you build more capacity you're building more capacity not just in the number of ports that can dial in, but [also] in the capacity to service the customer with mail and news and other features.

For an analog POP, traditionally you've got a bank of modems. If you are going to do any kind of sophisticated routing you need to have a quality router in there. That router is used for your backhaul, so you're going to be aggregating all your traffic from all your modems into a local Ethernet, and then you need to take that traffic and bring it back to your backbone operation. That's what the Cisco router is for.

You need a CSU/DSU to go with it; that's just to terminate the T-1. And you need some kind of terminal server that takes the serial data from the modems, handles the PPP translation, and creates Ethernet packets that then are routed through the Cisco. Then if you are doing a distributed architecture you have to have your servers down at the POP, and ideally you also put some kind of network monitoring like an RMON into your POP so you can do proactive monitoring.

So this is kind of a traditional POP. The thing I've always hated about traditional POPs is they have lots of wires. Yes?

M: The bank of modems you talked about, what is the ratio for a thousand customers?

Bob Berger: The question was, with a bank of modems what are the ratios to customers, the number of modems to number of customers?

That's kind of a business decision; it depends what kind of service you want to offer. It also depends on the scale. It turns out that as your customer base grows and as the number of modems grows, you start winning better with statistical utilization, meaning that if you have ten thousand customers, having a hundred lines will win, whereas if you have a hundred customers having only ten lines might lose. We are operating from about a five-to-one ratio to about an eight-to-one ratio, depending on the local customer range. We are still relatively small; we've got about 1200 customers.

With the traditional POTS POP — POTS stands for "plain old telephone service," and it's actually a technical term — ideally you still bring in the analog calls on the T-1. If you're going to have a bank of modems, they're in boxes now that you can get from U.S. Robotics that will take the T-1's in and demultiplex them, and then you have the bank of modems. From the T-1 you bring out twenty-four phone lines that go into the modem, [then] to the bank of modems — you have 24 modems. Then those modems have twenty-four RS-232 lines that go into the terminal server, and the terminal server then handles all the PPP translation and sends it off to the router, where it then is taken to your backbone operation or to the Internet.

This is also the model of a single POP. If you're just doing a single POP, you go directly to the Internet. If you're doing your own multiple POP architecture, instead of the Internet there, that would be your backbone.

[For] the POP that we use, we've built a modular POP that we believe is very scaleable. We push as many of the services out to the POP as possible, so when the customer tries to get their mail, they get it right from the POP; when they get their news, it comes right from the POP. That helps both in terms of the responsiveness to the customer, and it also helps us distribute the load so that a single point of failure doesn't wipe out all our customers. And as we add more POPs we add more capacity, so it is a really nice architecture.

Because we manufacture the POP we can deploy it rapidly. We just have a few standard POP configurations. We build them in our factory, and we can deploy a whole region in just a few weeks. We have just deployed into L.A., and the longest lead item was finding the real estate; actually deploying the POPs was done in just a few weeks. And we put out seven POPs. We also can support both analog and ISDN with the same hardware, and it has a lot of features for doing remote management.

So the kind of elements that are in our POP start out with the CSU/DSU and router that we use to backhaul the traffic over frame relay to our backbone operation. We then are using the Ascend Max, which is an ISDN hub router. This is a nice box because it can take in four T-1's that have ISDN signaling — which is called primary rate interfaces — and those calls can come in as either analog calls or ISDN calls. It has built-in digital modems to translate the analog calls, and it can support up to 48 simultaneous analog calls, or 96 B-channels of ISDN, or a mix of the two. So that's a nice box.

Then we put out a Sun Sparc 20 in each POP, and that handles all the mail and news, the DNS, things like that. And then we put a terminal server in there, mainly to be used for remote monitoring. We have all the console ports of all the devices hooked up to that terminal server, and then we can remotely log in either over modem or Telnet and access all the consoles. We also have a power control so we can reboot any of the devices remotely.

Then finally we have an RMON in there so we can measure the traffic both on the POP's Ethernet as well as in our backhaul T-1, so we can watch the traffic and can scale up the bandwidth as we need it, or add more capacity. And with POPs it's the real estate thing: it's location, location, location. The constraints are finding the twelve-mile radius that covers your territory in the most efficient manner, as well as finding the COs, the "central offices," that have the facilities you need. [For example], we need primary array interfaces. Then you want to find a place that's not too expensive; but it tends to be expensive anyway. So then that's pretty much the hardware picture.

In terms of the kind of services that you have to offer, it is basically the suite of functionality that is brought to you by TCP/IP. At the bottom is your connectivity options; we have gone through that, pretty much. You can supply any one or all of these services to your customer. You have to really think about the network design requirements; a lot of people get started just putting a UNIX server and a router in and they think that's all they need, and then they discover the multi-homed routing, the complicated internal routing, things like that.

And then [there's the] capacity planning. The worst thing that can happen is that you're successful; you know, you've got your T-1's, and now, oops — you need 10-megabit pipes, and that changes your whole network architecture. So you really have to think about, from the beginning, where you want to go and how you're going to scale it.

Peering is the issue we talked about of how you're going to get connected to other Internet providers.

The core of IP is, of course, routing. BGP is what you use for your backbone routing; I can't stress how important it is to have someone that knows how to deal with BGP if you're

going to have more than one connection to the backbone. As soon as you go from one to more than one the level of complexity of routing increases dramatically. And I have been surprised at how — there's basically, I get the feeling, a hundred people in the world that really know how to do it, and they all are scrambling continuously; they all have beepers, and they're all always just keeping the network running in the background. It's great if you can find someone that knows about that, or can connect you to someone who knows about that. Again, if you're going to have multiple POPs you need to have some kind of sophisticated [routing] — you can't use RIP. A lot of people put their networks together and they use RIP, which is the basic routing protocol that comes with most workstations and things like that. It is really easy to get started, but think of it as spaghetti routing; it doesn't scale at all. So you have to use something more sophisticated, like OSPF. Yes?

M: What about RIP Version 2?

Bob Berger: RIP Version 2 will be better, but I still wouldn't base my internal network on it. But you still need to do RIP for your customers; your customers can just use default routes to connect to you, but internally you don't want to be using any default routes or static routes, or just the minimum number.

Then you have to think about how you're going to allocate your IP addresses. For instance, each POP is going to have to have its own chunk of IP addresses, because you're going to want to set it up that how you route your internal network is based on what addresses are associated with the POP, and that boils down to allocating the addresses to your customers.

We'll talk a little about the domain name service system. If you are going to offer your customers the ability to have their own domains, that means you're going to be their domain name server; so if you're going to have a lot of customers with their own domain names, you have to have a very robust domain name architecture, so you want to have multiple servers and you have to really think about having lots of DNS files. We found — we were surprised, and we overloaded our directory. Normally you put all your domain name tables in one directory, and what happened was it exceeded [our directory size]; just the fact that the UNIX system had to go and do all sorts of work to just do a stack on that directory slowed down the whole domain name service. So you have to really think about the architectures of scalability again.

And you also have to worry about the reverse look-ups, and that gets back to how you manage your IP addresses. Mail is probably the most used service by your customers, and so you have to really consider it ultra mission-critical. You just can't lose mail; customers get really upset when that happens. That is one of the reasons why we both distribute our e-mail so that it is out on the POPs as well as use RAID disk arrays to carry the mail spools, plus doing standard backups on top of that.

So you have to put — it can't be a side thought. You will have to offer POP mail for customers that don't have a server at their site — which is most of the dial-up customers — so that POP mail allows them to dial up, connect, and kind of suck their mail down to their host. But you also have to support SMTP just for your own internal mail network, as well as [the fact that] some of your customers are going to want that. SMTP is the normal mail delivery system that is server to server.

UseNet News is another service that takes a lot of resources on the part of the Internet service provider but is considered an elementary service to the customer. You have to decide what kind of software you're going to use; there are the older ones, the B-NEWS and C-NEWS, and we are using INN, which has kind of emerged as a standard right now. That is a pretty big package, and you usually need a news wizard to really keep it running smoothly. You will also need to get news feeds, but that is a lot easier than Internet feeds. A lot of times your

Internet provider will give you a news feed, or you can find someone else who is well-connected to give you a news feed.

There are over twelve thousand newsgroups at this point, and the news spool is pretty big. If you want to keep more than a few days of news, you need just gigabytes of storage, and all the issues of having — basically the lights are always blinking on the disks for the news feed. So it turns out to be an area that can cause a lot of problems for a provider.

Then you have the case where if people start spamming and it happens that one of your customers is a spammer, that's always exciting... So you have to be ready for the fact that you might get deluged with mail and news messages.

M: What does "spam" stand for?

Bob Berger: The question is, what does "spam" stand for? I don't think it is an acronym, particularly. It is basically when someone sends a message to all newsgroups, [even though] that [message] has nothing to do with the newsgroup. That infuriates all the readers of that newsgroup, as it should, and then they will usually mail-bomb the spammer. And if the spammer is your customer, that means that you're dealing with the mail-bombs. I will talk a little bit about why you have to consider that when you do your terms and conditions.

What has emerged recently is that people are now expecting that as an Internet service provider you will also provide them with a place that they can put their Web pages. We are seeing a lot of people now including that as part of the basic service, that their customer gets 10 megabytes of storage on a public server at the Internet service provider's site. That is called a "shared server," where you have one or more servers that would have many customers' Web pages on it. This now kind of opens you up to — you're almost like a shell account for this, because people need to be able to potentially log on to that server to manage their files, things like that — so you now open yourself up again to having all the problems of a shell account, which is password management, hacking, managing resources, load balancing... But, on the other hand, the market is kind of demanding that. Hopefully we will see some tools that will allow people to remotely manage their Web page without actually logging on to the server. There are a few products out on the floor that let you do that.

People also tend to want to have anonymous FTP sites. It is not really too much of a problem to allow them to export or to publish files with FTP; it becomes a problem if you have an FTP site that people can upload to that's anonymous. We discovered that there are pirates, software pirates on the Net, that will find anonymous upload sites and use them as drop-off points; they will download gigabytes of illegal software onto your disk and then announce it to everyone, and suddenly you will first of all discover that your disk is full, and then [find that] you're getting this unbelievable traffic. So that's kind of one of the dangers of having open upload sites for FTP.

The shared server can be a nice business also. You can give people the minimal 10 megabytes, but then you can offer more robust servers or less densely populated servers for a charge, and charge people to put their business pages up there. Even nicer, if you have the capacity, is to sell co-located servers. Assuming you have built a robust network with some good bandwidth to your Internet backbone, and you have the space, you can rent space in your machine room where people can put in their servers and be connected to the backbone at 10 megabits per second. There is a nice economy of scale for both the customer and you to put that in; you can easily charge \$500 per month on up for that kind of service. Of course, it is another business, so you have to be ready to support that business.

And then of course everyone wonders about security. As an Internet service provider, the most you can really do is practice good Internet hygiene. You have to be on the Net; you

can't put your servers and things, your public servers, behind your firewall. But you can do things like packet filtering; As a matter of fact, you really should do packet filtering, so that you protect your customers from "spoofing." This word spoofing — where people will change the source address of packets and be able to sneak them in as pretending to be someone else — that is a very easy thing for you to protect against by just putting particular filters into your routers.

The other major thing you should do is use what's called "TCP wrappers." For all the services there is a package called TCP Wrapper, and it allows you to control who can access what service as well as be able to log every access to every service. It doesn't really stop them, necessarily, but it at least gives you the ability to know if you are being hacked, which is the first step.

You, of course, want to firewall your own internal applications, but the servers and routers and things like that that are public can't be firewalled. You want to internally use some kind of encrypted password system, *Cerberos* or *NIS+* or something like that, so it at least means your own internal passwords or something like that aren't always flying around in open air.

And in terms of services, you can offer to your customers firewall services if you have the expertise. Or, if you don't have the expertise, find someone who does and use them as a partner, because your customers will always be concerned about security. There is not much you, as an Internet service provider, can do yourself except what we have talked about; but you can offer them kind of hand holding to secure their own network. In the future I think we are going to see some standards that allow all the packets that go across the Net to be encrypted. Yes?

M: Can you talk about *Cerberos* versus *NIS* versus *Radius* versus *TACACS*?

Bob Berger: I think it depends what you're doing. The kind of architecture we have, where we are using routers as the access point, kind of makes us use either *Radius* or *TACACS*. We use *Radius* because that is what they supported at the beginning; and that is actually a pretty nice package. *Radius* is what allows for when people connect to the router with PPP, the router is presented with their user ID and password. The router then needs to know that is this a valid user, so it queries a server called *Radius*, or *TACACS* — a server that runs on the UNIX system, that has the actual database of user information — and then [this server] will report back to the router that it is valid or invalid. It turns out it also can be used to control all the parameters on a per-user basis with the router.

TACACS is an earlier version of that, and it sort of doesn't have all the features of *Radius*. They now came out with *TACACS+*, but I am not familiar with that. And *Cerberos*, I believe, is more an infrastructure that can be used throughout your network to carry security information; and *Radius* can actually interoperate with *Cerberos* for a kind of hierarchical authentication. But this is getting into a pretty sophisticated arena.

As I was saying, the encrypted packets I think are going to be kind of the savior of security on the Net; where people will be able to create virtual private networks between users by encrypting the packet stream between the users, so that prevents snooping and assures authentication of traffic. There is some standards work being done by the IETF to standardize [this] in a particular way. Today you can buy custom or proprietary things from a variety of vendors; I see some of them on the floor. But it will really become useful when it is a standard and it will be embedded in the stacks and the hardware.

[There's] something that when you first get started doesn't seem like a big deal: setting up user accounts. Just edit some files and they're set up; but when you start getting down to

[the point where] you're adding twenty users a day, or a hundred users a day, that doesn't work real well. Just the volume becomes problematic, and the amount of errors that are introduced starts being a contributor to your tech support load. So you really want to create a system — and unfortunately today it's pretty much that you have to create the system, as opposed to buying a system — to manage the whole order-entry process, the whole customer setup, password management, billing, clocking of the usage, allocating address space, setting up the mail... It's a lot of things you have to do every time you add a user, and you really want to automate that.

The *Radius* database I mentioned does generate billing information, so it actually produces start and stop records and durations; but you still need to be able to process that for billing, so you have to be able to [track it]. Basically the *Radius* database on each POP is producing megabytes a day of billing information, so you have to be able to cope with that stream, kind of bubble it down and port it to a billing system; and then there's the usual billing the customer, collections, and accounting systems... So this gets back to [the fact that] you're going to have to somehow bridge the internal operations to the normal accounting operations, so that's an area that we found to be a big investment.

Legal issues. Being a techie you sometimes forget about these, but they're really critical. Terms and conditions are really important. It kind of gets back to the issue we talked about, [the issue of] spamming. If it turns out one of your customers did a spam, and you didn't have anything in your terms and conditions that said you can't do that, you'll be open to being sued if you kick them off. But if you think about it, there's two things: one, think about the things that can happen like this; and the other is that as an Internet provider you have to think about some of the weird things people are going to do on the Internet, and [decide] if you personally feel okay about it. If you don't, you should put that into your terms and conditions too.

It is really important to talk about netiquette; you really want to be able to enforce that. If you do a terms and conditions, make sure your customers see it, and ideally somehow accept it — though a lot of people are just using kind of a shrink-wrap approach on that. And then I also strongly recommend getting real lawyers to review the stuff, to review your corporate stuff, your incorporation papers. If you are doing anything larger than just a small little POP, you really want to make sure you have some legal counsel on how you set things up. And it is worth investing that up front [rather] than later.

In terms of finance, in building an Internet service provider you're basically being a phone company; it is a utility and you have to invest money, and a lot of money, before you will really start getting returns, potentially. I strongly recommend having an experienced accountant/controller/CFO type person, at least as an adviser if not on staff. There are a lot of business issues that are as sophisticated as the technical issues.

And again, capitalization. Most businesses fail for being undercapitalized. It is real easy to go into this thinking "Oh, I can do this on my Visa." It's really — it's a big deal if you're going to do anything larger than one or two POPs. It's just very capital-intensive. We are just about to complete our first outside round, and we're raising five million. We put up about three million already.

M: Eight million dollars for twelve hundred customers?

Bob Berger: Yes. We just closed the second round for the expansion. The question was [a statement of] surprise at us raising eight million dollars and having twelve hundred customers. The thing is, we built our infrastructure to support ten thousand customers. That's why I'm saying that you have to spend a lot of money before you get a lot of money. If you are —

M: Even at ten thousand customers, that's \$800 per customer. If you're getting \$30 a month, it's going to take you six years to recoup your money before expenses. Doesn't make sense.

Bob Berger: He's debating on the wisdom of how we have done things. Basically, this is part of my point.

You have to spend money to be in play. You have to build a much greater architecture than you think you do. In other territories you might be able to get away with being a smaller provider for a while, but the market is accelerating so rapidly... I'll go into that in a minute.

Actually the next item, the national ISPs — the people you see here, PSI, UUNet — their capitalization is at somewhere between 40 to 100 million dollars, and none of them are making any profit above their expenses; they are all building out, and that's kind of what you have to do. And we are about to see the entry of the RBOCs and AT&T and those kind of people, and they have got billions.

So we're going to see — there was a niche in the past where you could sort of bootstrap your way in; I mean, NETCOM started in a guy's living room. That's past. It's just like the semiconductor cycle; you might be able to find some niches in some territories, but it is very rapidly becoming a capital play. Yes?

M: Do you think it is a good idea or a bad idea to offer services or resell hardware or equipment to your customers?

Bob Berger: Good question. The question was, is it a good idea to resell hardware?

M: Or to do services, setting up their own Internet access.

Bob Berger: That is actually inherent in our model. We developed basically a two-tier distribution where we sell through VARs and resellers. We sell all the hardware as well as software and services, and then the VARs also can sell their own integration services. Is that what you're asking?

We'll also talk about something else at the end. In terms of business issues, as I said, the technology is only a small portion of doing an Internet service business. Sales and marketing, finance and operations are as important, or more important, especially as we have now transitioned from the early adopters to moving to more mainstream. You just have to have complete support and operations; it is a full business. You have to be able to manage resources. And the market niches are being filled really fast. This has to be the fastest-moving industry I've ever seen; it makes the PC revolution seem like it was in slow motion.

I mean, I don't know how many of you people were at the original Internet World, which was only two years ago, but it was like an amateur event. And you can see what kind of activity is there now, the kind of players that are in it. It's no longer one that can really support much bootstrapped operations.

And I have found personally that people issues are a big one. I mean, this doesn't have as much to do with Internet as with starting a business. The technology is much easier than people; people are much more complicated. It's really important to choose your partners well. It's really easy, if you start something with a friend, that they might not be your friend for that long.

You also have to be really concerned about stock. In a startup company, stock doesn't seem like that big a deal; you know, your friends say that they'll contribute all this stuff... And then if you're the only one putting in capital, you really have to tie stock to capital. Stock options are really good as an incentive mechanism.

And then, finally, it's really important to get the best people. A lot of people think they can save money on people, but you always want to hire people smarter than you, especially when you're starting a business. People are going to have to do a million things at once, so you need people that can really excel under pressure. In terms of people, just in terms of numbers of people you need, just to give you an idea, I think your network operations and tech support really has to be robust to begin with. You have to very quickly go to 24-by-7 support, so that works out to something like seven shifts at least. You really need seven NOC operators at the minimum, and you need to have some really strong network engineers.

We talked about the issues of routing; I mean, news and mail can be almost full-time. Again, it really depends on your scale, but the 24-by-7 becomes kind of a nut that is incompressible.

Tech support is an area that can grow without bounds. Two is really the ultimate minimum, but as your customer base grows your tech support load can grow. And the more you can invest in other things like your automated turn-ups, and software that makes it easy for people to connect, that will reduce your tech support growth. But people perceive your company by who they call on the phone, and what kind of response they get; so that really is kind of the goodwill of the company, how good your tech support and customer service is.

Customer service is more the non-technical support — the billing questions, changes, resolving problems. So you need to again have a certain scaleable number of people to do the customer service.

Sales is an area you have to invest in, because again you want to boost your growth. Your question about the size... One of the mistakes was that we invested a lot in getting the core network and didn't invest the same time in sales, so the sales didn't follow or didn't parallel the buildout. You really have to invest early in the sales and marketing, [and have] at least one excellent person plus outside services. And that is going to have to grow as you grow.

Finance and operations; I was surprised how big that was. You generate a lot of paperwork, a lot of billing, and a lot of purchasing. Including the CFO, it's a minimum of three people. And it can expand.

Then [the amount of] time [from starting up] to market. From the point you decide that you want to start doing this, there's a lot of things that take longer than you expected. I believe it can be easily six months from your start to when you're really going full bore. Again, it depends on the scale; if you are doing a single site, that can be brought down significantly. When you are doing multiple POPs you have to really worry about the real estate, getting the telco to get the lines in — that always takes a lot longer. Getting them to work takes a lot longer. I was amazed at how the phone companies don't have it together. The one hope that the phone companies won't take over the Internet is [because] they don't know how to do data.

And [then you have] the business issues, setting up the accounting. The more you can do that up front, the accounting, the customer turn-up, all that stuff, the faster you can grow and the better your quality of service is.

So I end [with the question], are you really sure you want to be an Internet service provider? It's a lot tougher than it seems at first blush. One of the things that we have come up with that is kind of interesting is [the fact that] we have done so much of this work, we are now starting to OEM a lot of the architecture we have done. We are right now focusing on mostly out-of-the-country opportunities; but if anyone is interested, they can contact me at this address and talk about OEM possibilities, where we have a lot of this stuff turn-keyed.

But good luck to those who really try. It's exciting and it can be fun, but it is really challenging and there will be some ups and downs. So thank you; if you have any questions, we

can take a few minutes to answer questions. If people could come up forward, if they want to ask questions, it would be better.

M: Will you be publishing any of your graphics on your Web site?

Bob Berger: Yes, they will definitely be published in the CD-ROM, and I will do my best to put them on the Web as at least an FTP; it's a PowerPoint presentation. Thanks.

ACCESS PROVIDERS

INTERNET ACCESS PROVIDERS: A BEGINNER'S GUIDE

SPEAKER

Joel Maloff

President, The Maloff Company

Joel Maloff: Good afternoon. I think we will get started now. For those of you who are just coming in, I think there are one or two seats left, so we might be able to find a place for you. I have never spoken in a circus tent before, so this ought to be an experience.

I want to welcome you to this afternoon's session. My name is Joel Maloff. I am a consultant. I have been involved in the Internet business for quite a long time, having been executive director of the Big Ten university research network for three years and a vice president of sales and marketing for Advanced Network & Services, one of the largest Internet providers at the time in the United States. So I have been involved with this for a while.

For the past two years, have been acting as an Internet consultant assisting end user companies that are looking to use the Internet for business purposes and additionally assisting what I refer to as Internet access provider wannabes, companies that are trying to get started as Internet providers. So I have worked in a variety of different ways.

The session we have planned for you this afternoon consists of three portions. The first portion is my comments as a consultant talking to you about what to look for as end user organizations in picking an Internet access provider. What do you need to know? What do you need to understand in order to compare apples to apples and be able to understand the value from various providers? That will last until about 2:30 or about an hour or so.

We will then take a break and then come back and have a panel of distinguished Internet access providers in fact from around the world. We will have the vice president of marketing of UUNet Technologies. We have one of the key directors of BBN Planet. We will have one of the key personnel from Pacific Bell, a regional Bell operating company. We have an Australian Internet access provider and a Canadian access provider. Each of them in the second session will have an opportunity to present their own views on what you ought to be looking for in their opinion in picking an access provider. They will tell you a bit about themselves and they will tell you a bit about what they think is important.

That's the second session. And then in the third session we think we are going to have a little bit of fun. I will come back and act as moderator. Each of the same providers that I mentioned a moment ago will be on the panel and we will throw them questions. You from the audience will have the ability to do so as well. Each provider will have one minute to answer that question. And heckling is encouraged, from you, or the other panelists. And depending on how it goes, if it's not too bloody and I'm not in a benevolent mood, we will decide at the end who we think won.

The idea is to have a bit of fun but to give you the opportunity to see something that you don't often see, and that is access providers standing up against one another. So instead of comparing apples to oranges, you will hear what they believe their arguments are and how they try to refute one another.

That's what we have planned for this afternoon. And in my presentation, as I mentioned, I am going to be talking about my views as a consultant and how I have assisted people in selecting Internet access providers. There are three major areas that I am going to cover: what the Internet is from an access provider's standpoint and how it is important to you as end users; who the different types of Internet access providers are.

And you often hear people use the term "Internet Access Provider" and mean it in a very general way. My view is very different. There are a variety of different types of Internet access providers. It is important for you to understand their different strengths and weaknesses.

I should add, by the way, if you haven't noticed already, I'm in the holiday spirit. All of my slides are in Halloween colors. I couldn't find an icon of a pumpkin, otherwise I would have used it. But I thought it would be nice to at least remember today is Halloween. And I'm not in costume!

The second part of my discussion will be, what are some of the services that access providers might offer and how are they important to you, so that you again know what are you looking for and are you comparing apples to apples. And the last portion is to talk about some of the specific qualities and traits that different access providers have.

So these are the topics that we have planned for your discussion today and, again, as I mentioned, I think it will get interesting as you get an opportunity to hear after I present a consultant's view what the access providers think and then have them have the chance to go head to head with one another.

One final comment before I launch into the comments. Many of the comments that I make are in my new book that has just been released, *Net.Profit*. It is available on the show floor at the Quarterdeck booth. I have tried to again provide information in the book from a business perspective: what businesses are looking for, how they are looking to use the Internet, and then how do you go about obtaining Internet service.

That's the commercial for the book. No more on that. Let's launch into what are you looking for when you're picking an access provider.

I'm sure you all think you know what the Internet is today. We have been talking about it for the past several days at this conference and it's gotten an enormous amount of hype. What is important to recognize is that the Internet is not a thing. In fact, in many of the sessions that I do I will ask the question: Does anyone know who owns the Internet? Occasionally someone in the back will jump up and say "God!" It gives a whole new perspective to routing problems when you think about it.

The fact is no one owns the Internet. The Internet is a network of networks or a community of networks. It works because each of these individual Internet access providers agrees to interconnect with one another. In the earlier talk this morning you heard about the various kinds of meet points, NAPs, Network Access Providers, the Commercial Internet Exchange. These are places where these Internet providers connect with one another. So it is important to remember that the Internet is a community. There is no one provider that offers Internet access everywhere in the world, so it is important that all of these providers connect with one another in a relatively seamless environment. We'll talk about how that occurs in a bit.

When I look at Internet access providers, as I mentioned in my opening comments, I see a variety of different types of providers. The first category that I will talk about are those providers that I classify as backbone-oriented. What this means is that they have multiple nodes or sites that they have connected to themselves using private leased lines. In the case of the slides you can see Advanced Networks & Services, ANS, my old company, which was acquired by America Online. They had for a while the backbone service that was used by the National Science Foundation. It consisted originally of thirteen and then ultimately eighteen nodes throughout the United States and finally extending into Hawaii. Each of these was connected to one another so that if you were connected to ANS in Boston and wanted to communicate with someone connected to ANS in Washington, you would be communicating entirely through the ANS network or on-net. If, on the other hand, you wanted to communicate with someone that

was connected to UUNet or BBN Planet or to MCI, you would have to go through one of these meet points or connections that I referred to.

So when we look at how Internet service providers design themselves, we look at what kind of on-net or backbone facilities they have.

This is a listing of some of the major backbone providers that are there today. A year ago there were perhaps three or four. Now there are many more. As you can see, ANS/AOL is still there. AT&T has recently announced backbone services, as has IBM. PSI and UUNet have been around for a long time; they are the oldest of the commercial Internet providers and recently both have announced aggressive expansion plans internationally.

One of the trends that we are seeing — I mentioned this in some comments I made in another talk yesterday — is a move towards domestic American providers extending internationally. If they do this on their own, it will be somewhat difficult. If they do it in partnership with others, I think we will see a much broader global explosion. That's already starting to occur.

Some of the others that you can see, NETCOM has been around for quite some time, and CompuServe. Now, I am going to talk about the on-line information service providers as a second category in a second. But I believe you should look at CompuServe as well a bit differently. It is not all that well-known, but CompuServe has had a private network division offering frame relay private corporate networks for some time. That has given them a leg up on some of the other Internet providers and some of the other on-line service providers that haven't done that kind of work in the past.

So again you need to look at the types of providers, what kind of network infrastructure do they have. And again just because a company has fiber optics as does an AT&T or an MCI does not mean that they have Internet nodes everywhere. It is important for you as end users to understand, how are these networks architected? Where are you going to be able to connect? How robust they are?

That's one type of provider. The second type of provider comes from the traditional research and education background. These include networks like CERFNet, the California Education and Research Foundation Network; Colorado SuperNet, VJNCNet and my old network, CICNet.

It's interesting. For those of you who have heard me before, I apologize for this, but I am often asked what CICNet stands for. It actually stands for the Committee on Institutional Cooperation, which was the Big Ten universities minus Purdue, plus Illinois and the University of Chicago, and that's a mouthful, so we chose to call ourselves the Committee on Institutional Cooperation. But again as you might tell with networks like CERFNet, NEAR Net, FAR Net, BIG Net, we tend to alliterize the names of our networks. We try to decide what we should pronounce our name as. The first choice was, we thought we would call ourselves KICK Net but some of our board members didn't like the idea of being kicked around. The second choice was SICK Net. Didn't seem like a good idea for a robust network provider. Third choice was CHICK Net. Lady board members had a problem with that one. And the last choice was SHEIK Net. One of our members is Iowan, went to undergraduate school in Iowa, and I think of hogs and corn, hardly chic. So we settled on calling ourselves CICNet, and got an award as the least creative name of a regional network.

These networks mostly were formed by academic computing centers of universities and were meant to serve students, faculty, researchers and staff. That comes from the mission statement of my network. Many of them tried to become commercial, and in the case of BBN Planet they have succeeded. They have actually taken former research and education networks and molded them into a business. Many of the other ones have not. And it is important when you are looking at Internet access providers to look at historically where do they come from,

what are their strengths, what are their weaknesses. Most of these providers tend to connect to other backbone providers. They may have a small regional backbone but certainly do not have a national or international backbone as the others that I have alluded to earlier.

Then the next type of provider is what I refer to as an Internet reseller. These are providers that do not establish their own backbones but rather buy capacity from a major backbone provider such as Sprint or MCI or Net 99, [ANS], which again was mentioned earlier. These are firms that will buy a connection into that access provider. Again, no backbone but they are reselling someone else's capacity.

So it is important to understand, how are they connected? Are they connected at one place? And think of this, for example. If I am an Internet reseller such as North Shore in the Boston area or Digital Express in Washington and in New York or DataBank in the Midwest, if I have a connection into Sprint and that connection fails, all of my customers are partitioned; they are no longer connected. There is no backbone. So the question to ask an Internet reseller is: How redundantly connected are you? Do you have connections to more than one backbone provider? Are you connected to Net 99 and MCI or Sprint or ANS? How are you connected? What bandwidth are you connected at? How robust is it?

As an example, there have been many people at this conference talking about how to start an Internet access provider. I have even seen companies talk about how you can acquire a 56 or 64-kilobit per-second connection and then sell 56 or 64-kilobit dedicated-access connections to your customers. I don't know how you can do that very well. What happens if that connection is cut? What happens if all of them are using it at the same time? Again, you as end users buying capacity need to understand what type of provider are you dealing with. Each of them has different characteristics and different advantages. We'll be talking about those as we go through.

In addition to the backbone providers, in addition to the research and education and Internet resellers, there are also a variety of other providers that are looking to become active in Internet access provision: Internet exchange carriers. These are the long-distance companies. We haven't yet seen an aggressive approach from cable and wireless, but I believe we will. LDDS/Wiltel is a major national and international facilities provider. They will be very aggressive. I believe both of these will be offering Internet access services.

But one of the points I would caution you on is that offering Internet access is not the same as offering point-to-point circuits or dial-up voice. It is not circuit-switched, it is packet-switched. Which is very different. As an example, Sprint has been involved in offering Internet access service for three and a half or four years. I do a series of research reports and I know that early on in the first twelve months Sprint offered only dedicated access, had a total of about thirty customers, three zero, after twelve months. After twenty-four months they had about seven hundred and after thirty-six months they had about fourteen hundred.

The point is I know the time has changed, the market has matured. But the learning curve to train your sales force if you are a telco and large is quite lengthy. Think about it. If you have ten thousand salespeople and you can train thirty or sixty a week, how long will it take you to train every one of your salespeople? And let me assure you, selling TCP/IP and Internet-based services to business is not easy. Not all of the salespeople out there selling telco services can spell data, let alone sell it. Sorry. I was one of them.

It is important to understand what you are selling, and I believe there will be learning curves. In addition to the interexchange carriers or IXC's there are local exchange carriers looking to be active in the Internet provision business. These include the regional Bell operating companies or internationally the PT&Ts, local phone companies who want to be able to offer these services. In all cases the learning curve is likely to be larger, longer than they think it will be. It is important for you as consumers to be educated consumers, know what you are asking

for and be able to compare apples to apples. We'll talk about what to ask for as we go through this presentation.

In addition to the telephone companies, the regional Bell operating companies or the large independent telcos here in the United States or PT&Ts worldwide, there are also what are referred to as alternate access providers. These are companies that build fiber-optic or microwave bypass networks that will bypass the local telephone companies. Perhaps the best known is a company called Metropolitan Fiber Systems, MFS. They have built bypass fiber-optic facilities in more than twenty cities in the United States and several internationally. You have the ability to connect to these providers and bypass the local telephone company. It is a simple matter for Metropolitan Fiber Systems to connect via leased line their New York-Boston-Washington-Chicago locations and create their own closed private network that never touches the local telephone companies. So it is important to recognize these kinds of providers are emerging as well here in the United States and internationally.

Lastly we need to look at the cable television companies. They already have embedded plant, physical facility. There have been tests going on for Internet access for more than three years. Continental Cablevision here in Massachusetts, Jones Cable in Alexandria, Virginia. The cable modem is becoming more effective now. It works. The price is coming down.

Again, there will be a learning curve. People who operate cable-TV companies don't understand a whole lot about how to do interactive services, especially something as complex as the Internet. Nevertheless, they will be offering services. So you've got all of these different types of providers out there.

In addition to that, you have the information providers, America Online, CompuServe, Prodigy, and Delphi. It is interesting to note, perhaps three years ago the on-line service providers had a choice: Do we try to resist this Internet thing that is developing or do we try to embrace it and become part of it? And it is very clear that in most cases they have chosen the latter.

Today CompuServe is part of the Internet. America Online is part of the Internet. I do a great deal of work internationally. I was in Manila in the Philippines not too long ago. I had the ability to log into a local Internet access provider in Manila, bring up my connection and then bring up my America Online software, indicate that I wanted to use TCP/IP to connect, and I was into my America Online account, able to read my mail just fine, even though America Online offers no access service at the moment outside of the United States. And yet I was able to use it.

All of these services are becoming part of the Internet. America Online through GNN just announced a stand-alone Internet service yesterday. CompuServe has had one for some time with SPRY. Again, all of these providers are now part of the Internet. You have options. You have choice.

What is critical for business is to understand as you look at this melange of providers, what am I looking for? Am I looking for ease of access? Am I looking for technical proficiency? Am I looking for multiple locations around the world? I have a company, I have branches in twenty cities throughout the United States and ten countries internationally. I want one provider that will help me use those. How do I pick? Today there are a few providers that can offer you some of that service. Arguably, there is no provider that offers access everywhere. So again you need to look at the different types of companies that are offering service. Do you want to use a small entrepreneurial company? Or do you want to use a very large company? And just because they're large, just because they have large amounts of fiber in place or satellite transponder time does not mean that they are proficient in Internet.

Again, you need to explore that and understand it. I'm not asserting they are not. The point is, don't assume that they are.

I think it is important to understand that there are different types of connection. I know this is basic but it is important to understand that not all providers offer all types of service. There are two basic types of Internet connectivity service: dial-up, which comes in dumb and smart varieties; and dedicated access.

Some providers offer only dial-up service. Mostly these tend to be smaller Internet resellers. Some large providers, such as my old company ANS or Sprint, only offer primarily leased line or dedicated services.

Again, it is important to identify what is important for you. Are you looking for a dial-up account that is inexpensive, relatively easy to use? Are you looking for a business- quality account? Are you looking for support from people to help you understand not only how to use it but where to look, what resources are there? What are you looking for?

If you are looking for dedicated access, do you have a need also for dial-up services? Again, I think it was an almost fatal flaw for ANS and Sprint not to offer dial-up services because there are many, many businesses today that are looking to use dial-up services as a way to try it out and then move into higher-bandwidth leased line services. As an example, I mentioned the Internet report that I've done in the past. Between 1994 and 1995 SLIP, Serial Line Internet Protocol, or smart accounts in the United States grew an average of 35 percent per month compounded. Leased line services grew at 7.1 percent per month, down from 13 percent a month a year ago.

Again, I attribute this to having saturated most of those businesses that knew what they would do with a leased line connection costing ten, twenty, thirty thousand dollars a year by the time you add in all of the costs of going to dial-up accounts. I have many very large clients, life insurance companies, for example, that have no direct Internet access but they have thousands of dial-up accounts. What is likely to occur over the next several years is what I refer to as the pig in the python effect. All of these people using dial-up accounts for business now are going to migrate into leased line or dedicated access services over the next several years. We are going to see this continued growth and pulsing, rippling effect as dial-up and dedicated access move back and forth.

Again, it is important to understand that the dial-up services I am talking about are not the traditional residence/consumer quality. These are businesses who might buy fifty or a hundred or a thousand dial-up services at a time in multiple locations around this country and around the world.

You as an end user need to examine what are my requirements? What am I looking to accomplish? What kind of provider do I need? What qualities of service am I looking for?

I mentioned the report that I've done, and it is actually available on-line. It is a bit dated now. The research was done in February of this year. It is available. The executive summary and table of contents are free of charge. The report is downloadable using First Virtual capability. For the most part, unless you really, really need it, I don't suggest you buy it right now, it's changed so much.

But the point is there is information out there. I still get requests from around the world, even though I tell people the information is fairly dated.

Now, again when you are looking at access providers, remember that there are a variety of providers out there, everything from the BBSs that are Internet resellers and offer dumb shell accounts, text-only, to more graphical interfaces using Mosaic or Netscape and offering you those tools. What is it that they are providing you when you sign up? Do you get shareware tools? Do you get a professional package? What are you receiving when you sign up?

What kind of services do they offer? Are they offering FTP, Telnet and e-mail? Not all providers today offer you all of those services. You might wish to use Telnet but find that your provider doesn't offer it. Again, it is critical that you think through before you go to an access

provider and say what's your price, to ask, rather, what do you offer? What are the services that I can obtain? Do I get all news groups or do you in fact limit the news groups that I can reach?

I may want to do a variety of research work and I may want to receive all fourteen thousand news groups. Does your access provider offer feeds for that? Do they offer you the ability to manage your ListServ capability, again using notes, or Gopher, or World-Wide Web? What is it that the provider offers to you?

You can read about all of these. I'm not going to belabor the point. It is important to identify that there are many resources out there. You need to know what's useful for you.

Again, if you are looking for a provider, when they offer dial-up you need to ask: Is it UUCP? Is it SLIP? Is it PPP? Is it a shell account? Is it ISDN? There were some interesting definitions as to what ISDN meant this morning. The one that I always liked was "It still does nothing." The fact of the matter is after about fifteen years it actually does do something, but you can't get it everywhere. I happen to live in a rural area in Michigan. It's a great place to telecommute from. I do a lot of work there. But ISDN is not available.

I will tell you, however, that I was able to log on to Ameritech's Web server, identify my area code and exchange and find out that it wasn't available without ever having to ask somebody. I know I got my information a lot more quickly than if I asked someone at Ameritech for ISDN availability.

Leased line service. If you want leased line services, what bandwidth does the provider offer? And then at this point it becomes critical to know what bandwidth do they have going out? Again, if you want a 56-kilobit per-second connection and that's the only type of connection that your provider has going out from him to somewhere else, what good is it?

You need to understand how robustly they are connected. Again, if you are a business, you want to have a migration path. If you gain access to 56 kilobits, do they have access to the next level, fractional T-1, full T-1, 10-megabit or T-3? Again, all of this means that you as a business need to think through your requirements first, recognize that this is a business planning process; explore which access providers can meet your needs; get proposals from them on those needs, addressing each of these areas.

In addition, when you are obtaining service from an access provider you want to know what other kinds of services do they deliver. If I give you a dial-up account and you are a new user, a novice, you need some sort of interface. Am I giving you shareware services? Am I giving you Trumpet WinSock? Am I giving you Eudora in a shareware version? Or am I providing you Internet in a box or Quarterdeck's Internet suite or FTP's software or NetManage from the Chameleon package? What are they providing? How well is it supported? What kind of support services do they offer?

Another area we look at is posting services. This is a whole separate topic area. But if you are looking to establish an anonymous FTP server, a Gopher server, a Web site, you may — as many businesses are today — look to outsource that so that does not even sit on your property. What is important about this is that if you have a host, a Web server, you must have dedicated connection to that server. A Web server doesn't work with dial-up very well. The last thing you want is someone getting "network not reachable" or "domain name service lookup failed."

So what many companies are doing is outsourcing this and saying to vendors I would like to put my Web information on your server. You are responsible for making sure that it is secure. You are responsible for making sure that there is sufficient bandwidth. All of these issues.

Now, it is interesting. I often have people in these sessions say, well, if I put a Web server on the end of a 56K and it is not connected to anything else, I really don't need any other security. I mean, what can anybody do to me?

I don't know if any of you saw the *USA Today* news yesterday, but last Thursday Rodney Dangerfield's Web site was hacked into and somebody replaced Rodney's picture with a picture of a naked woman. They didn't say whether or not the lady looked like Rodney or not. Whatever. He's still not getting any respect.

The bottom line is, your Web site can be hacked into. All of these things are important, so when you are looking at services that you require, you need to consider all of the factors that go in. Am I going to host it myself? How much bandwidth am I going to need? What applications am I going to be running? All of these things get back to looking at this as a business issue, with the tools being some of the available services from within the Internet. So it is important for you to start with, what am I trying to accomplish and then, what services do I need from the providers that I am exploring?

The last one on this slide is training. If I deliver a T-1 to your site, am I going to assist you with training? Am I going to help you with configuring it? What services do you need? If you are a brand-new user and you're getting a SLIP account, will I come in and train your one hundred people that bought accounts from us? What kind of services will I offer?

And they don't necessarily have to be free, but they do have to be available if you need them. Again, it is important for you to understand, what capabilities do you have? What requirements might you have? And what are you looking for from your Internet access provider?

In the panel that we are going to have after our break you will have several Internet access providers from all over the world that will describe their view of their services. Remember, the Internet is a business tool. And it is my perspective as a consultant that it ought to be driven by you as the users. And rather than these providers coming up with technologies looking for a place to sell them, you need to identify what your needs are and explain those to the providers and let them respond to them. That works best, rather than just simply saying "Give me a quote." Because then you will have all sorts of apples and oranges; you won't know which compares to which.

Each of these providers has a different scope of services. First of all, do they have a clear and easy growth path? If you are looking from a business perspective to buy dial-up services with a plan for moving possibly into dedicated access or closed user group capability where you have a private network within the Internet — which is possible — does the provider that you are looking at have these abilities? Can they grow into dedicated connections later on?

Again, you are looking for a provider that is extensible and that is compatible with your growth plans.

Do they have 24-hour by seven-day-a-week management and monitoring services? Let me assert to you that one of these beepers does not constitute 24-hour service. It is important for an access provider who is business-oriented to have the ability to monitor and troubleshoot and be able to correct routing anomalies, loss of connection and so forth, before you even know you have a problem. And it has to be 24 hours, seven days a week, because the Internet is global; it is worldwide. You may very well have people looking at your Web site from Australia or Hong Kong or India. It is important that that service be up all the time. You may have researchers that are working at 3:00 o'clock in the morning. The last thing you want is someone to be in the midst of a very extensive FTP download and have the circuit fail, have the service go out. That simply isn't acceptable in a high-quality professional business environment.

But you need to ask these things and you need to ask, what constitutes 24-by-7 service? Does that mean that you have people on-staff? Are they doing active monitoring, active testing?

Are they waiting in a reactive way for someone to call? What does 24-by-7 mean to your providers?

Customer-service orientation. You know, it's interesting. Most of the Internet access providers who were around early on, the research and education providers, some of the backbone providers, all came from a very technical perspective. Absolutely fabulous technically. You want to talk about BGP? They can talk about that all day long. You want to talk about CIDR? They'll talk about that all day long. But if you want to talk about how do I find that archive somewhere else, "Look, you're bothering me, go away, I don't have time for this. Go talk to somebody else or buy a book."

That is not a customer service orientation. We're a business now. The Internet is an industry. You as end users have a right and an obligation to demand service, and that means they must have people to support you. It is expensive to do it properly, but I see no other way.

Customer service is going to make the difference in which access providers win and which access providers lose. It is important for you to drive that. Domain name service registration. You want to use xyz.com as your Internet address. Well, how do you go about registering that? Can someone help you do so? You want to know, can they assist you in that process?

You have a new product line. You want to have a unique demand based on that product line. Will they assist you? How much does it cost? Will they charge you for it? Is it then transportable? My address is Joel@maloff.com. If I don't like my address, I take maloff.com and go somewhere else. Can you do that with the domains that are provided to you? Again, how supportive, how responsive are they to your needs? Do they make suggestions? Do they tell you how they can assist you or do they simply say "Here's my price list, good luck."

Again, I believe that this is a business and you need to demand quality from the providers.

Announcement of Web sites. If they are going to host your Web site, recognize that just because you have a URL Web site address does not mean that Yahoo or Web Crawler or Lycos or All-In-I or any of these other search tools know you are there. You need to be announced. If they are going to host your site, will they assist you in announcing the availability of your site to these various tools? Again, looking for how easy are they going to make it for you. How much are they going to work with you in assisting you to make the transition from startup to implementation?

The last point on this slide I think is absolutely critical. Again, as I mentioned in my opening comments, the Internet is a network of networks. It only works if each of these network providers meets, connects, and interchanges their information and routes with one another. Now, these meet points are the Commercial Internet Exchange. The network access points, or NAPs, Mae East or Mae West or other bilateral connection points, or a BBN Planet, might meet with an ANS or an MCI might meet with UUNet and exchange their routes.

Again, remember that the Internet only works because these networks connect with one another. When you are looking at picking an access provider, especially for business purposes, how well interconnected is your provider? For example, are they connected at the Commercial Internet Exchange, exchanging their routes at that site in California? And are they connected to Mae East in Washington or a network access point in Chicago? Or are they connected in all of these?

From my perspective as a consultant there are three places that congestion can normally occur within the Internet. Remember, when you hear people saying the Internet is congested, I don't know what they're talking about. There is no one backbone. The three places are on-net within the existing Internet providers' structure. The modems are busy, their circuits are busy. That is one place where congestion will occur.

The second place that congestion will occur is at these meet points, where they are trying to pass their traffic. So, again, do they have redundancy? How many of these do they have?

And then the third place that congestion occurs is at the destination sites. If Yahoo is very busy or Lycos is very busy, it doesn't matter what the rest of the net is doing; that server, that site is heavily trafficked and you will experience delays. So again try to understand how well-connected the providers that you are examining are to the Internet as a whole.

Another point that I believe is important is personal compatibility. It is very important to understand the type of provider that you are dealing with. If you have been using AT&T you have a Tariff 12; you're very comfortable with dealing with them. Again, you want to ask hard questions, but it may be a no-brainer. You've already got connectivity into them, it works; that's fine, let's do it.

On the other hand, you may have some very sophisticated requirements and you may want to deal with a smaller, more entrepreneurial provider, so you explore them. Are the providers that you are dealing with professional and responsive and capable? Are they technocratic and demeaning? I don't understand why customers will stay with a provider that tells them they're stupid. And I've seen it. Internet discussion groups have actually seen access providers read the riot act, that's a nice way to put it, to their customers on-line. That's a great way to win friends and influence people!

The point is you're looking for a professional-quality provider.

Lastly, it is important to explore how many key people these access providers have. This last point is one that isn't often thought of. But as an example, if you have a leased line connection and you are experiencing routing anomalies and problems and their one engineer that understands it is out fishing in the middle of Lake Erie, you're in trouble. So how many key people do they have? If they have a technical support staff, how well backed up are they?

Again, all of these are hard questions that these providers need to be asked. And the more critical the Internet is to the conduct of your business, the more crucial the answers to these questions become. If you're just using it for dial-up, who cares? I mean, you can live with it. If you have your company's business riding on this, you have your secure parts databases that your sales force is accessing to try to be able to close a three-million-dollar sale and all of a sudden your network is partitioned and I can't get to it and there's no one that can help, you're in big trouble.

So again it is important to assess how critical these various functional capabilities are within each Internet access provider that you're exploring.

I mentioned earlier that I work as a consultant. One of the approaches that I am involved with a great deal with my clients is the development of requests for information. There are really three different types: request for proposal, which means here is a set of our requirements; we would like you to propose to us how you can meet those requirements.

The second is simply a request for information: We are not in a position to buy something today but we simply want to know how many locations do you cover. We have twenty locations throughout the world. What is your capability to do?

And the last is a request for quote. I need a T-1 delivered to me in Boston at area code 617, exchange 492, and I need it in three weeks. What is your price and can you do it?

Those are the three different kinds of formal procurement tools that are used. I think it is important to look at these, because a formal solicitation process forces you as the end user and buyer to sit down and think through the issues that I have been expressing to you this afternoon. What do we want? Why do we want it? What are we expecting that provider to offer? What are we looking for? What are the criteria that we are going to use to assess the responses?

You put all of that into a formal written document. You then announce to all of the prospective providers that might be of interest to you that you are going to announce this solicitation and get them to respond. You then have the ability, because they are required to respond in your format, to compare apples to apples and see the answers to those questions. If they don't, they are nonresponsive, I throw them out. That way you get a very clear comparison among them of what each can do.

I think it is important because a formal solicitation will force the providers to give you not only the best prices but the best suite of services to try to win your business. And if the provider won't respond to you in a formal fashion, then they aren't professional enough to carry business into the '90s and the next century to come.

Again, I believe in a formal solicitation process. It has worked very well. I have done this extensively for Web outsourcing. One of my favorite projects is the Discovery Channel. Discovery On-line, www.discovery.com, started out with this process. We met more than a year ago, went through the entire proposal evaluation/implementation process. It came up in July of this year. I believe it's one of the best sites on the Internet and it is because we spent the time to think it through, examine what we want and get vendors to respond in an organized fashion. I think this process works and ought to be considered if you are dealing with large requirements.

A couple bottom-line conclusions. I think the Internet is a wonderful business tool if you take the time to think about what it is you are trying to accomplish, what it is that you are expecting from an access provider. I absolutely believe that users must drive the technology, not the other way around. I'm sorry. Internet vendors can come out with all of the inter-whatever services they want. But if it doesn't meet a business need that I or my clients have, I'm not interested. I mean, maybe you'll get me interested because I like to play, but it is not something businesses are looking for.

It should be the other way around. You as businesses should be telling these vendors, what do you want to see, how do you want to see it delivered, what quality of service do you require, and at what price. You are in control. All of those providers that I showed you earlier mean one very important thing to you as end users. It is a buyer's market. You have the ability to drive the marketplace. I strongly encourage you to take advantage of that.

That's it for my presentation. I will answer any questions that you have on what I have prepared and spoken about. And again, for those of you who came in late, again I want to mention that we are going to take a break in a few moments or so and come back at 2:45. There will be a panel of Internet access providers. Each of them will have about ten minutes to present their views on what they believe you ought to be looking for. Then following that we will have our debate where each of the providers will be thrown questions, and we encourage you as the audience to participate.

So if there are any other questions, I'll answer them. Yes, sir?

M: I thought it interesting you didn't have in your requirements anything about security or firewalls.

Joel Maloff: That's a good point. The comment is I didn't have any comments about security. And actually that's an oversight on my part. I do believe that, especially for dedicated access, security is important. But that starts again with a security plan. Each company has to consider what they are protecting, who they are protecting it from, and then how much they're willing to spend on security. You then have the ability to start within your own environment looking at various pass code administration policies, looking at firewalls, application layer gateways, physical authentication devices. Again, that's a whole topic in itself.

I do look for access providers to offer some of that. But quite often I look for outside providers as well. What is important again is for you as businesses to be able to understand what you need.

Other questions?

M: Is ANS here? Are they in trouble?

Joel Maloff: ANS is not here, no. The question is, ANS is not here. Are they having any troubles? Well, the answer to that is America Online is here; they own ANS. The ANS backbone is in fact the underlying backbone in AOL Net today. As to the question of are they still focusing on offering direct end-user connectivity, it does not appear so.

M: [Inaudible]

Joel Maloff: We might want to talk about ANS off-line. Any other questions that I can answer for you? Yes, sir?

M: You mentioned congestion at the meet points. I was wondering if you could go into a little bit more detail about who actually operates those and where the points of demarcation between the different providers are.

Joel Maloff: The question is: Of the meet points that I mentioned, especially concerning congestion, who operates the meet points and how are the connections occurring in those.

Each of them is very different and they tend to be almost ad hoc. The network access points, for example, were funded by the National Science Foundation. There are four of those, operated by Pacific Tel., NYNEX, Sprint, and Metropolitan Fiber Systems. Those are the four. They are located in California, Chicago, Washington and New Jersey. And essentially in those cases you have to bring a T-3 or 45-megabit pipe to that site and then you have to arrange with the other providers that are connected to do what is called BGP or border gateway protocol peering to exchange your routes. So all that really is a site managed by a contract to the National Science Foundation to permit the research and education networks to have access to other providers. Not that many access providers either want to go into T-3 or have done so yet. Some of them have, but not all of them.

In addition, the Commercial Internet Exchange is a trade association that essentially consists of a router or series of routers using FDDI ring that multiple providers are connected to. It is important to recognize, let's say I am a small reseller and I am connected through Sprint. Sprint then interfaces at the Commercial Internet Exchange with many other providers. They do not have to accept my routes because I as the small provider am not a member of the CIX. Now, I can pay the \$7,500 and be a member of the CIX and then they will accept my routes. I have not bought a leased line from Michigan to Santa Clara, I'm still using Sprint, but now they have agreed to accept me.

The meet point issues tend to be individual. Each of the providers negotiates with other providers to accept their routes. It's not the way I would necessarily build the network if I were doing it from the ground up, but it does work and it has been effective thus far. I hope that answers the question.

Other questions?

All right, we're going to take a break now and come back in about fifteen minutes for our panel. Please come back. I think you'll enjoy the rest of this session. Thank you very much.
(Applause)

ACCESS PROVIDERS
INTERNET ACCESS PROVIDER'S PANEL:
WHAT DISTINGUISHES THEM FROM EACH OTHER?

MODERATOR
Catherine Smith
President, UUNorth International, Inc.

PANEL
Joel Maloff
President, The Maloff Company
Mark Fisher
Marketing Director, Pacific Bell Internet Services
John Curran
Chief Technical Officer, BBN Planet
Alan B. Taffel
Vice President of Marketing, UUNet Technologies
Rael Kuperholz
Planet Internet (Melbourne, Australia)

Joel Maloff: Good afternoon, and welcome back to our Internet access provider session. My name is Joel Maloff. The second part of our session is going to be hosted by Catherine Smith, who is from UUNorth International, the Canadian Internet access provider. Catherine is going to be hosting a panel of several international Internet access providers. Each of the providers will have an opportunity to speak with you and then at the conclusion of her session, we will again have a short break and come back.

The same panel of providers will remain and I will act as moderator, taking questions from you or posing questions directly to the panel. Each of the panelists will have one minute to answer, and heckling will be encouraged from you and the other providers. We will give you the chance to hold their feet to the fire. So we hope that this is going to be an entertaining and informative portion of our session.

So without any further ado, let me introduce Catherine Smith, president of UUNorth International.

Catherine Smith: Thank you, Joel. Good afternoon, ladies and gentlemen. This is where you have probably the most fun of your entire time at Internet World. So do I!

I am an Internet solutions provider. I'm a little bit different than your Internet access provider. I am a little bit different than your ISP just for services. I started UUNorth about five years ago when in Canada nobody knew about FTP, TCP/IP. Canada is still very much virgin territory. At least now that we still have a Canada left! Which is nice to know.

In the United States people were very busy selling TCP/IP and they were very knowledgeable about it. Canada is about two years further behind and we're 10 percent more expensive for access costs. As an Internet access provider I was one of the ones who was standing around saying, well, wire is fine, but how can you use it for business? What do you as a user want to use the Internet for? I was intrigued by how it worked, why it worked. But how could this work for you?

We at UUNorth are an organization of, actually, five of us under what we call Canadian Internet Alliance. These are organizations who are committed, with preferences and specialties and expertises in the various fields. We are not one organization trying to peddle routers, wire

and services to one person. We are a group of people with specific expertises providing coordinated solutions to you as an individual.

Should you only need Web services, we can do that for you. We do business applications. We start you off from a beginning dial-up account straight up to T-1 services. We help you each step of the way. If you need, we can come in, set up your computer. If you are an individual and you don't want training but do need some help and expertise, we will have you come to my home where I work and say, "All right, sit down, show me where you are having problems. What don't you understand?" So that I can better service all of my customers.

Understanding how the Internet is going to be used is crucial in the way that I can conduct business. We do all sorts of testing with people and it is not uncommon for me in my newsletter to say "Call me up, we have some software that we would like you to test. Let us know if this works for you. If it doesn't, why doesn't it? What do you see then that could work for you? What are the good points? What are the bad points? Do you like the documentation? Is it something that will be useful?"

This is what UUNorth's philosophy is and has been for the past five years. I am not interested in talking alphabet soup to people. Most of the people that I hire all have business degrees and commerce degrees and have been in business for over ten, fifteen years, who are all committed with networking interests in helping people communicate.

And that's the key to what the Internet is, especially with business. It is helping people communicate. It's not a fad, it's not a whiz-bang, gee golly, cool idea. It's something that will be here for a long time, that will become invisible. And all of this will go away. It has to, in order to help you work effectively. The media is going to have to calm down, be quiet and look at how people are successfully doing business and growing.

The people on the panel that I have are respected in their fields. They have been in this business, they have gone through trials, tribulations. There was a gentleman up here talking about how much money it was going to cost if you wanted to be an Internet service provider. These people have been spending this much and a lot more developing their businesses, developing communication skills, to help you as the end user better communicate.

I am going to call them up and they're going to have ten minutes. Now, ten minutes isn't very much, so they'll have to talk quickly. They will have to speak succinctly; they will have to get their points across to you. You, on the other hand, as an end user and critic, if you like, in this respect, will have to listen carefully and make sure that you got all the points so that when you come back in the third session to ask them questions, you'll nab them and you can make them feel as uncomfortable as you like. Unfortunately, that applies to me too!

I would like to call up as our first speaker Mark Fisher. He is director of marketing for Pacific Bell. He is the telephone representative on our panel. I would welcome him and I will leave you to your presentation, Mark. Thank you very much.

Mark Fisher: Thank you.

Good afternoon. Again, I'm Mark Fisher, here with the Pacific Bell Internet Services. And as a quick ten-minute discussion about what we think is important in terms of choosing an Internet service provider, I want to touch briefly on our vision for the Internet market as it relates to California and how we want to add value in that market and some of the things that we think are important toward providing good Internet services in California.

Very simply, the Internet has of course grown in such a way that the interest from both consumers and small-business market as well as high-end business has led to a point where many are interested in a very simple, very affordable, convenient solution to get them connected to the Internet. For those of you who have spent time in any of the sessions here, it is on the one hand a very complex task. But on the other it is something that I believe for the

sake of the growth of the Internet going forward, we need to provide a very simple solution, one that doesn't take a great deal from the customer's perspective in terms of resources and one that is affordable so that they can start in a small and reasonable way using the Internet as an effective business tool, and that we are there for them to grow as their needs change and grow over time.

I just want to talk briefly about the role we see Pacific Bell playing in the Internet. We have of course a long-standing tradition of providing data communication services throughout California. We operate the largest frame relay network and SMDS network in the state of California. Really, the Internet is a very logical and at the same time a strategic extension of a portfolio of services that we offer to businesses, folks at home and at work throughout California. Again, leveraging on the networks that we operate today, adding the functionality of Internet name and address routing and basic Internet software packages through our technology partners, the solution becomes complete. We offer a convenient, one-stop solution.

California, as you know, is a hotbed for Internet activity. By many estimates, approximately 30 to 40 percent of all Internet traffic either originates in or terminates in California. That notwithstanding, there is a huge market available in the state of California: small businesses, consumers who are looking for a very simple cost-effective solution that will grow this market substantially.

This is sort of indicative of the role we see ourselves playing. Admittedly, it is a single datapoint, but it is very consistent with the kind of research that we have done about what our customers are telling us they need. We have talked to many customers who now believe their Internet connection is as vital to their business as any other telecommunication service they get from us.

By and large, those are customers who are coming to us saying, We want you to offer this service. We'd like to think of this as just one more service in a portfolio of communication services that are being offered. We want to come to you to make it this a single, one-stop shop, a very convenient solution, a very affordable solution. And we view you as the kind of provider who can provide that on scale, in a reliable and responsive way to customers throughout the state.

I want to really focus on this simple slide but talk to it a little bit in terms of the elements that we see customers talking to us about, their needs, and how we can support those toward an Internet connection.

I have mentioned convenience and simplicity a couple of times already. We are absolutely convinced that what is needed in the market today is a very simple, very straightforward solution to easily connect the small business. If they want to start with simply an e-mail account and use the Internet in that fashion, they need something that is very simple to get them on-line.

Up until very recently customers in most cases, in many cases, looking for an Internet connection, would find they would go to many different places to get that solution and really were forced to build it on their own. They went and found the right hardware, perhaps the right software. They went to an Internet service provider, and they may have come to us for an Internet connection.

We really want to consolidate that into a single stop where we bring the access, the transport service, the Internet hardware and software through our technology partners into one place so a customer can come simply to us and let us handle that solution, and make an extension again of the portfolio of telecommunication services we already offer.

I mentioned cost-effectiveness. We feel it's very important and the feedback we have gotten from customers, of course, is that they want an affordable solution. And again the idea that this scales as a small business or a larger business first starts using the Internet for

something as simple as e-mail; their applications then grow and change. They begin using it for Web services. They may or may not need hosting services, and over time they may grow into an ISDN-based or dedicated-services connection to the net. We want to be there serving them and letting that service grow with their needs and with the applications they are using on the Internet.

Also, a comprehensive solution. I mentioned already these four elements that we think are essential as the building blocks to a complete Internet solution. We want to be able to do that in a comprehensive way. I will mention again as I talk briefly about our technology partners, we think we have brought that together in one place and made it convenient for customers.

Finally, a single point of contact. And I'll bridge this with the next idea, which is a California focus. I've already mentioned that California is a hotbed for Internet activity. We absolutely believe that our commitment to the California market, that our existing account teams who are out there serving customers with their voice and data-service needs can extend that service to include Internet, and they are in a position to leverage again the relationship that exists with these customers and add to that a valuable service in Internet connections. They are in a great position to explain the dollars and cents, the sort of mini-business case of connecting the customer to the Internet that helps a small business decide this makes sense for them.

This is the kind of discussion, this is the kind of relationship we have had with customers, business customers, throughout the state for some time. And it makes perfect sense then to add Internet to this portfolio.

Also, a reliable, responsive service and support center. We see a very strong need for a California-focused, California-based service and support team so that customers at home or at work when they have a problem, when they have an issue, they can call us seven days a week, twenty-four hours a day, there's someone there who understands the problem and is committed to working this out. This is, again, an aspect of the business of communications that we have been about for quite some time. Bringing the right level of customer service and support to this solution is something we are absolutely committed to do.

I mentioned some technology partners. Of course, at the same time understanding our strengths, the basic business of communication services, we recognize there are places where we need technology partners to help us create the right solution. Cisco Systems has been a long-standing partner of ours for access routers at the high end for business. Also, Sun Microsystems with the Netra server line providing a complete Internet-based server for the business location. And in the software area, Netscape Communications, a partner of ours both in the server area for products we're using in our Internet but also, more importantly, creating a customized dial-up package for the consumer, for the small business, whether it be via analog modem-based dial-up service or whether it be the ISDN. We see this again, the Netscape partnership, as essential to making this easy, convenient, and affordable for customers.

And finally, addressing the issue of security, our partnership with Sun Microsystems using the Firewall I security product will help business customers establish a secure presence on the Internet.

Very briefly just in terms of target segments, this isn't terribly sophisticated in terms of analysis, but it makes an important point. One is, we are committed to the marketplace in California. Consumers, people at home, people at work who we think will need the Internet, will want the Internet services, a convenient, affordable solution in both places, we want to provide that solution. And then as well to the point of being able to grow along with the small business's needs, we want to be there. We are certainly in this for the long run.

As the small business begins to use a simple e-mail account and evolves into much more sophisticated Internet-based services, we want to be there to grow with that customer. First, to

bring them on, help them understand the power of the Internet, and as time unfolds, to be there as their business grows.

There's a brief discussion of our services; this slide touches on the dedicated services. And I have a handout that is a little more extensive than the slides I've just gone through. I will leave that there on the podium. As you leave, you can pick up a copy.

I certainly thank you all for the time to talk about our vision for the Internet. Again, making this convenient, affordable. Our commitment to the California marketplace is, we think, an essential part of the solution for the customers we serve. Thank you. (Applause)

Catherine Smith: He did very well, didn't he? Right on time. Thank you very much, Mark.

I now am going to introduce John Curran. He is chief technical officer of BBN Planet. John, if I could ask you to come up, please. Thank you very much.

John Curran: Good afternoon, I'm John Curran. I'm the chief technical officer for BBN Planet.

Some of you might have heard of BBN. BBN is Bolt, Beranek & Newman. We have been involved in the Internet for now a little over twenty-five years. We built the first Internet. We are located in Cambridge, Mass. I am happy to come over here for the afternoon.

I hope you will bear with me, because I'm going to be speaking a little fast. Ten minutes is not a lot of time, so I hope you bear with the accent and the speed at which I talk. It's customary in the area.

I am not going to talk about BBN much. Many of you are BBN customers or, if you have walked the show floors, you have seen them. What I am going to talk about is selecting and evaluating Internet providers, some of the things we feel are prime differentiators, things you should be paying attention to.

So without further ado, as Joel mentioned earlier today, the Internet services marketplace breaks into a number of segments. Dial-up, SLIP/PPP services, dedicated Internet services, Internet security solutions and Web information hosting are sort of the prime segments of this marketplace. There are different criteria for every segment. You've got to figure out what you're buying first; then you can decide what criteria apply.

I am going to go through each one very quickly and talk about some of the characteristics you want to ask. In the dial-up marketplace, many people offer dial-up access. You can get dial-up access locally through a local dial-up provider; you can buy nationwide services. They vary by speed. They vary by price. Some of your dial-up services are very cost-effective. Because they are local, there's only a local toll charge or, if you have the right billing plan, potentially no charge.

Some of the services are not necessarily as cost-effective. You have 800 numbers in use; we have 900 numbers in use. Many people are paying more for their telecommunications charge to dial into their provider than they're paying the provider. You pay \$19 a month for Internet service and then you pay a local toll charge of \$40 a month worth of usage. You have to pay attention. Some of these services are flat rate and they are flat rate up to a count, ten hours, twenty hours, twenty-five hours, thirty hours, and then they bill you each hour beyond.

When you go to decide what you want for Internet services, one of the questions you have to ask yourself is: What do I think my usage is going to be? How much Internet service do I need? In the dial-up marketplace the thing that gates that is how much time you spend directly on-line pulling down information.

There's an addressing issue. One of the concerns that happens is that if you want to have a reliable Internet address, the same Internet address each and every time you dial in, you have to ask your provider. And this is an important issue. It turns out we now have many customers who have their sales force out on the road or they have people who are traveling

out on the road and they want to dial in and they want to have a predictable Internet address associated with the user. That is a very difficult thing to deliver. But it allows you to open up your network and permit communications with that one customer.

Most of the time when you dial into the Internet you're anonymous, meaning you're just as if someone next door dialed into the Internet. For this reason, if you are expecting something else, if you are expecting to have a predictable Internet address, you have to ask. If you want a domain name, one of the most interesting things we're seeing now is companies who come on-line and say, "Well, I thought if I got connected to the Internet I'd get food.com." No. You have to ask. If you want a name for your company, it's called domain name service and it is an essential part of being a business on the Internet. Don't buy a dial-up service that doesn't give you your own name.

News services and mail services are also required. Things you have to ask your provider.

Now, we don't actually provide a lot of dial-up services. BBN Planet provides dial-up services to its corporate customers to meet their needs, but we don't sell certainly on the individual marketplace. You can see dozens of providers who offer individual users access to the Internet. Our focus is on the commercial market and the organizational market, principally in the leased line area, the dedicated access to the Internet.

We now have over fifteen hundred organizations that are receiving BBN's services, and those can be delivered in a number of ways. You will hear this from many providers. You have to ask what you're looking for. There's leased line services, frame relay services, ISDN services. Which is actually a form of dial-up, but if you are a business, an ISDN service that connects very quickly can be in some ways indistinguishable. SMDS services, which is switched multi-bit data service, which is a very-high-speed service. And we are seeing the emergence of some ATM-based IP services now. Depending on what speed you want, you want to ask your provider, Okay, I'm interested in T-1 speed. What's my choice for a T-1 leased line? Now, if you offer SMDS, what's my choice for T-1 SMDS service? Now, if you offer frame relay, what's my choice for T-1 frame relay?

Those will be different services. And they are going to have a different underlying rate, so it is important to ask. You can't compare two services that are slightly different. The performance may be similar, but the prices are going to be different depending on how you connect.

One of the most important things to find out is how the networks are engineered that you're connecting into. There is a term used in the industry called an over-subscription level or a fan-out level. Which is, if you have a bunch of connections into a point of presence, how much bandwidth is serving that point of presence?

Those are questions you should be asking. You should be asking, how much capacity is going into the POP that I am being served out of? What is the aggregate customer demand? Now, I know this may sound like something you don't really care about. And you don't. People value the Internet for connectivity first. So if you're just going to get connected, it may not matter. Now, when you actually go to use the Internet, when you actually try to move that image file to your business partner, when you actually try to get involved in a business solution on the network and the performance matters, this is where the differentiators come in.

A lot of people can connect you to the Internet. The question is going to be, at what performance. So you want to ask. You want to ask what their over-subscription level is. You want to ask what the backbone looks like. You want to ask where they interconnect.

For those people who were here in an earlier session with Joel, he mentioned the interconnect points, the NAPs, for example. You should know where your provider is connected because it does affect the bandwidth. One of the interesting things about the

Internet is that people talk about the available bandwidth as if it's just like a circuit. I buy a T-1 circuit from here to Cambridge; it's a point-to-point circuit. In the Internet we don't have two points; we only have one. We have you and we have the entire Internet. Your performance between you and another site in Cambridge, you and another site in Washington, you and a site in San Jose, and finally you and a site going international are going to be different.

You can't buy bandwidth that is committed to the entire world. Actually, you probably could, but you wouldn't want to pay for it. Okay? The reality is that the Internet relies on an over-subscription level to allow you to reach a host in Beijing without paying in advance to have that capacity.

I am going to try to move very quickly and talk about some last aspects of dedicated services and hosting services.

Routing and addressing. Has anyone heard about Internet addresses? We have an issue. The Internet needs addresses in order to connect you up, and there is a finite number of them, so you want to ask some questions when you come on-line. They may seem minor. We've seen companies get snarled in them two years later. Which is: Do I own my Internet address? When I change providers, does my address come with me or am I going to renumber my local area network of a hundred hosts? It's worth asking.

Equipment. Does the provider provide the equipment? Should you provide the equipment? There are major differences in prices, and so you have to make sure you're not comparing a quote without equipment to a quote with equipment. Important issues.

Packaging with other services and, finally, redundancy. We have a number of high-performance customers who are now asking for redundant capacity, well-engineered links, so that they can offer their Web sites high capacity or they can have a high-availability solution. We build those routinely. BBN in addition to selling Internet services to a large number of organizations does a lot of responses of exactly the type Joel mentioned earlier, the RFP-style response where someone is seeking a custom solution.

So you want to ask. If you think you have a high-availability requirement, it's something worth asking. It may not be commonly dictated, but a good provider knows how to build that.

Now, dedicated Internet access is not the entire market. In addition to worrying about the bandwidth levels, you have to worry about what your pricing is. We have a shakeout occurring in the industry today. As your bandwidth goes higher and higher, it is more difficult to predict reliable performance with fixed pricing. The legacy of the Internet is fixed pricing. Five years ago it was all a flat-rate annual, no matter how much you used. You will now see the emergence of providers at higher bandwidths who want to charge you based on your actual usage. And so that's a hard thing to decide.

You want to make sure you're paying a fair rate, you're getting usage reports that say how much you're actually using. Depending on what you think your usage is, you can end up with a wildly different price. And so it is something you have to watch out for. On the other hand, the good news about a variable price is that we know as you make more use of the network, there's more engineering concerns. So there is both a good — There is a cutting edge in both directions.

Now, different providers take different approaches to where the service demarc is, where they accept responsibility for. BBN historically accepts responsibility to the customer's LAN. The network, the connection, the local circuit, the CSUs, the router are all ours for operational purposes. We configure it, we manage it, we monitor it. At 2:00 in the morning if something goes wrong you shouldn't be calling your provider; your provider should be calling you to say something's wrong and we're working on it. If you have someone who is proactively managing your Internet connection, you can put your services on it and not worry about how it's being watched.

Now, we also provide the configuration management. We operate the whole thing. We provide problem tracking, and we are responsible for on-site field service.

I would like to quickly skim through Web hosting and security services just to give you an idea of the issues involved.

Internet security comes in multiple flavors. When you get connected to the Internet you have to go looking. Think about different layers. Packet filtering. You can secure the network just by blocking certain packets if you know where all the hosts are. Application-level filters? This is something that sits between your network and the Internet and stops each transaction. A higher level of security. Ask what you're buying. And then finally for those people who are going to have a Web site you want to ask, if you're connecting to the Web, where's my Web server? What's the performance level? And the same questions you ask for dedicated access: engineering level, monitoring, response, ticketing, et cetera.

I would like to thank you for having me here, and I look forward to the questions.
(Applause)

Catherine Smith: Thank you very much.

I would like to ask Alan Taffel, who is marketing director for UUNet, to come up.

Now, we ask for your indulgence on this. We're going from Apple presentations now to a Netscape presentation, so we are going to give him a few minutes to set up.

I hope this is giving you some ideas of what all of our different service providers are offering. I hope it puts some questions in your mind for the next session so that you can pin these people down and get exactly what you want out of them. We have presented this for you. We have presented this to stir your thoughts, give you a better idea of how you are going to choose a service provider and what you should expect the answers to be so when you call your service provider tomorrow and ply him with all these questions, you will know and expect what his answers should be. And ask him if he can tell you precisely in ten minutes or less exactly what services he can provide you with.

Are you ready? Alan Taffel, ladies and gentlemen.

Alan B. Taffel: Thank you very much, ladies and gentlemen. As you can see, this presentation is a little bit different. Rather than being PowerPoint, it's actually an HTML presentation.

I was very glad to hear John Curran's presentation because he told you about the criteria you should be looking for when selecting an Internet provider, and I agree with everything that John said. Now I would like to assure you that there is in fact a provider that actually meets all those criteria. And that's obviously UUNet Technologies.

A little bit of background about us. We were actually the first commercial Internet service provider. In 1987 our founder, Rick Adams, had the idea that, gee, this technology which has been used in the government and for primarily research purposes would be a boon to businesses, and so he founded UUNet Technologies at that time. Today we are the largest Internet service provider to businesses. And we are one hundred percent focused on the business sector of the market. We don't spend a penny trying to woo consumers to our service.

We are also somewhat famous for being the builders of the infrastructure for the Microsoft network. If you are using the Microsoft network and you're using the Internet to get to the Microsoft network, you're actually going over UUNet Technologies.

Now, I mentioned that we have a focus on business. And what that means is we have to have the highest quality of service and we have to have value-added services that are tailored for business users. Let me tell you about some of that.

This will give you an idea of some of our representative customers. And sometimes people are surprised to find out that a lot of these on-line service providers are actually customers of UUNet and use our infrastructure, such as America Online, CompuServe; we already mentioned Microsoft. A lot of telecommunications companies fit into the same boat and we have many financial customers and many customers in all other areas. This is a very small subset of our customer base. We actually have well over eight thousand corporate customers. Not eight thousand individuals or anything like that, but eight thousand corporate customers.

Our network meets all the criteria that John described to you, but let me prove it to you. We have a nationwide — we're not just in one region — we have a nationwide backbone. It is a dedicated 45-megabit backbone. It's our own backbone. And I am going to show you a picture of that in just a moment. All of the links in that backbone are fully redundant. All of the switches in that backbone are fully redundant. All of the switches, all of the hubs are located in telco facilities with uninterruptible power supply. So we really are very, very serious about making the investment so that our service is a business-quality service.

And we are equally serious on the dial side of the equation, because business users require business-class dial services as well. One of the worst things you can have in a dial network is busy signals. We have engineered our network, at additional cost, obviously, but we have engineered it so that the network delivers what's called in telephony terms a P03 grade of service. That means there's a less than a 3 percent probability of getting a busy signal any time you dial up.

And there are hundreds of points of presence in the U.S. By the end of this year we will have 230 points of presence in the U.S. and another twenty cities internationally. All of our dial points of presence support all speeds all the way up to ISDN, not just stopping at 14.4 or 28.8. And all of our high-speed points of presence, even if they are not directly on the backbone, connect to the backbone at very high speeds like 10 megabits. We don't have any 56K connections from any cities into the backbone, as do many other service providers, so you don't have those local bottlenecks. Of course, we have 24-by-7 network operations and proactive monitoring.

Now, if this works right, I can click on that hyper-link and get a view of our backbone here. Sorry that's a little bit fuzzy on this video system.

One of the things I would like to point out to you is that we do have the most connections to other components of the Internet of any Internet provider in the world. We have more connections to other domestic points and more to other international points than any other provider.

Now, as a business you need a full range of options to get onto the net and then you need value-added services, so I will spend just a little bit of time on each one of those.

As far as dial-up options, as I mentioned, every port supports 14.4, 28.8, ISDN, and we have all kinds of usage billing schemes. For instance, at the show here we just announced a new scheme called Internet 9 To 5, which gives you completely unlimited access, unlimited number of users from a LAN to the Internet for a flat monthly fee during business hours, 9:00 to 5:00 Monday through Friday, \$130 a month, flat rate.

And then we have all the selections you could possibly want in terms of leased line and quite a few that are unique. For instance, our burstable T-1 service, which is actually our most popular service, allows you to have the full access of a T-1 pipe but only pay for what you're actually using, a concept that we borrowed from the frame relay world with the CIR. So it is much less expensive than other providers' T-1 services and yet you can use the full capacity of the T-1 when you need it. Very attractive option.

We also have a tiered T-3 service which is for people who need more than T-1 but don't need a full T-3. We can sell you access at 3 megabits, 6, 9, et cetera, all the way up to a full T-3.

In addition, we have I think every value-added service you could possibly need. At least we're trying. First of all, we will do turnkey Web hosting and content services. We have a Web server farm at our headquarters in Fairfax. It is co-located with a major Internet switching hub, which means that we can provide you, your Web site, with 90-megabit access to the Internet. Think what it would cost you to buy 90 megabits of capacity to the Internet. Of course, we're not going to charge you for that; we only charge for what you actually use, which is probably much, much smaller. And it turns out that our hosting services are about one-fifth the cost of doing it yourself. That's not 20 percent less; it's 20 percent of the cost of doing it yourself. And it is a completely turnkey solution. You don't have to buy any servers or anything else; we take care of everything for you. It is a lot less expensive and it is higher performance.

We also have a full range of security services starting with consulting, which we believe is very important. You should have a security policy that encompasses the Internet. Then we provide firewalls if you need to protect your internal resources, and we have encryption devices if you need to protect your data even as it is traversing the Internet. Finally, we have training oriented for either end users or for systems administrators.

That concludes my prepared remarks. I hope you've seen that we have gone to great lengths to provide a true business-class service for business users of the Internet with the most robust network available and the broadest spectrum of access options and value-added options. I think I ended on time. Thank you. (Applause)

Catherine Smith: We have left Rael Kuperholz of Planet Internet in Australia for our last speaker of the day. He has come an awful long way and we are very pleased to have him. Mr. Kuperholz will certainly let us know what life is like in Australia for an Internet service provider and I think he will certainly open our eyes. If you think that bandwidth is expensive here in the United States, it's expensive in Canada, but I think you will understand how expensive it is Down Under. Welcome!

Rael Kuperholz: Thanks very much, Catherine. Good afternoon, everybody, ladies and gentlemen.

I didn't have as much opportunity as the others to prepare a slide show. Neither did I have a laptop, having dropped it at San Francisco Airport on the way over, and so I thought I'll use a little bit of innovation or borderline on cheap because I like your vote, get your support. Not that necessarily many of you would want to dial international to Melbourne to connect every time you wanted to chat on the Internet.

So bear with me. It is going to be pretty much of a loose-form discussion and chat.

As you can see up on Netscape, I'm off our server in Melbourne. That's Integration Design, a company that's been going for just over six years now, and the idea is people and technology providing integration services. About three years ago we started getting asked a lot about the Internet and doing a lot of work for organizations wanting to connect to the Internet. And you probably heard that expression if you lie down with dogs, you're going to get up with fleas. And what was happening was, we were advising and recommending customers or connecting them to different service providers, and found that all the problems associated with pretty poor services was rubbing off on the way the customers were treating us or thinking of us and we were being tagged with the same mark.

So just earlier this year we decided to set up a new company. And hopefully the bookmarks will all be there. What we did was we set up a company called Planet Internet. And

Planet Internet's strategy has been to capitalize on the weaknesses of all the competitors, because the big Internet providers have been going for somewhere between one and two years. And I think that everything we looked at and decided that we're going to try to overcome with Planet Internet or were issues to avoid are all very much particular.

Now, I said I'm going to cheat in order to get your vote. I've brought something really special over here. I've got something that's probably more unique than anything at this show. It's a Planet Internet T-shirt. I brought one because I travel light. It's one Planet Internet T-shirt and it's for whoever stands up during the panel discussion and asks either the best question or gives me the best reason why they should own it. But there's only one other one: Joel Maloff. He came to Melbourne to fetch his. I've got one and then you'll have one, so that's how I'm going to cheat for your vote if it gets down to something like the Quebec referendum.

Now, the key thing is demystification, trying to demystify everything. What we found is that organizations, whether it's an MIS manager or an individual wanting to connect to the Internet, there's a lot of mystery associated with the Internet. So whatever you do, you have to be able to demystify the whole concept, demystify the technology, and make it as painless as possible. We also, like Alan said, focus on the commercial side of the business. But what we have found is in order to avoid litigation, more and more companies are becoming very aware of the need to have e-mail usage policies, corporate conduct policies for the Internet specifically to avoid things like breach of copyright, intellectual property, libelous statements, and so forth. So we capitalized on that and created a special package so that our commercial customers can offer their staff personal dial-up accounts at a major discount or subsidize that to what they can get via another Internet provider. And this way you're encouraging staff to present themselves as individuals via their personal dial-up accounts from home or wherever and utilize corporate Internet services for corporate business.

What was also said earlier on, you've got to have partners, technology partners. And we recognize that there's no point us setting up an Internet provider service using equipment that our customers wouldn't use in-house, so we based everything on a Rolls-Royce platform. We actually brought Ascend Communications into Australia three years ago, so we're using Ascend, Sun, Netscape, Bay Network, Cisco, and so forth; Hayes modems, if we have any, and that type of thing. So it's all very important to base yourself on the equivalent platform to what you would expect your customers to be on.

A few other quick ones I put together. If the only time you hear from your Internet provider is when you get the bill, then it's probably time to change. And if you get any handwritten communications, it is also I think time to change. These are all things, sort of weaknesses that we experienced during the last few years.

We've had the situation in Australia — I don't know; I'm sure it's happened here as well — if you've had Internet providers who've been badly hacked and their credit card or the customer credit card or accounting or billing details have been published on the net, then it's time to change. If you experience any downtime that is going to affect your business, then it is also certainly time to change. And as Alan said, you've got to be running on a fully redundant platform, fully redundant circuits and connections into the net.

Also, if your help desk calls do not get answered by the next day, then I think it's time to change. Somehow or another people don't tolerate anything worse or longer than that when it comes to support for any other aspect of IT, but because of the rapid growth and the poor service associated with a lot of Internet providers, customers are becoming almost used to long delays in getting back or hearing back from their help desk. So it's something that you do have to do.

As I said, we also have dual-homed gateways. People in the United States are very spoiled with endless bandwidth. Companies talk T-1's at all times. Alan mentioned that they've

got nothing less than 56K. We don't have anything less than 56K either, but it's what you put down that one 56K requires more than just innovation. It requires perseverance and so forth. It's about just over two million dollars per annum if you wanted a T-1 from west coast California to Melbourne. So we can't afford to expend bandwidth like you can over here. And it has forced us to become very innovative.

What we do is, we provide separate circuits for traffic going out international versus traffic that's on the domestic backbone. We also run, as I said earlier, on high-speed Sun Sparcs. All the software that we use, whether it is Web service software or anything else, is all fully licensed software. So like you want and expect your provider to have a 1-800 number for you to call for support and help assistance, we also have a 1-800 number that we can call when something fails. And I think that that is extremely important, considering that so much of the Internet is based on freeware and shareware software.

We use the Firewall I for customers' Web sites, co-located hosts and so forth, in order to provide the best level of security as possible. We also decided to provide not just co-located Web servers but something you want to consider commercially is, we looked at and have satisfactorily achieved co-located firewalls as well as Web servers.

So if you've got an organization that really doesn't want to fuss with it or develop any in-house expertise, they recognize that it's easier to place their firewall and their Web servers, and maybe they run a news server in-house, rather than in-house, outsource it to us and run it in a proper computer room and facility and environment with backup and a higher-speed connection to the Internet, particularly if their Web server is supporting the customer's worldwide base.

So we think that that's been something successful, well-received, and it's quite innovative. We do things like DNS registration both out of the United States as well as the dot AU for the Australian market or dot NZ for New Zealand.

The other thing is, all Web work and all Web hosting we do for customers is in fact not us licensing the intellectual property to the customer but we do it on behalf of the customer and ownership resides with the customer. So that if someone is unhappy with our service or for one reason or another want to take an outsourced solution back in-house, it is a case of asking for the disk drive or asking for the source code or HTML code or whatever it is that we've done for them.

We also provide comprehensive software suites I mentioned for all the staff of the commercial customers, et cetera. We put a range of PlanetPacks together that's got fully licensed software available for them to be able to connect. They don't have to know how to start downloading and so forth. At a senior executive level we are finding that it is still very hard for people to use PCs, let alone connect the modem up, get to the Internet, and then have to download the suite of software that they need to use to gain access. So we have written installation programs and a customized menu front end for them.

We also use interactive voice response for our help desk and fax back, and we have based our help desk — It's very important what a service provider is running his help desk on. We use a product from Remedy Corporation called *Action/Request System* that, from my understanding, most of the large Internet providers worldwide would use it. It's a superb product. It does things like autoescalation, automatically pages people if the autoescalation is still not gaining response. We interface the network management system directly into the help desk. And we also have a front end from Remedy called *AR Web* that in fact allows our help desk that's sitting over in InformLINK's database to be accessible only to our customers at or from home.

Say if they've got a problem that's not affecting their connectivity, they can actually access the help desk direct; they can see what the flow of the issue is, how it's tracking through

our organization, how it's been rectified, and all the results of that information goes into a knowledge database with a free-form text search facility so they can come in and see maybe someone else had this same problem and it's been resolved. And that way it cuts down on their voice traffic coming in to us and in to our help desk.

As I think John mentioned this morning, he went to the Ameritech Web site to see if he could get ISDN access to his house. I thought that was pretty neat. And I suppose it's the same concept in a much smaller way we're trying to achieve.

We use uninterruptible power supplies, backup power generators, 24-hour backup air-conditioning; as I say, dual ISDN feeds. Everything we use in Australia is ISDN-based with frame relay leased lines and PST and access all available via ISDN, so it keeps it much simpler on our end and gives us an affordable as well as an adequately reliable service.

One of the other things that we have done is, we have created a little bit of a chat show. We have tried to encourage our customer base, be they commercial or the staff of our common commercial customers, to talk to each other; and we try and create a really friendly environment. And we've found that that also cut down on a lot of calls coming into our own help desk but at the same time the customers got a much quicker answer. And so we encourage people to — We've got like the equivalent of a closed news group and we encourage people to post some of the queries that they might have of a very wide and general nature, not specifically specific to the Internet or problem proper. And this way everybody who's connected to Planet Internet is in fact sharing the ideas.

Just two other, couple of things. Catherine mentioned in her opening remarks that she's an Internet services provider providing services. Alan also mentioned the fact that he is providing consultancy services. We have found that the strongest part of the Planet Internet business has been the fact that it is a spin-off from Integration Design. So you've got an organization that is very accustomed to dealing with multi- billion-dollar or five-million or three-million- dollar organizations in providing services.

Just two last things and then I'll get off and we can start the panel. I noticed just setting this up today that we are an extremely innovative but a very truly international company, and I was actually very impressed to see that one of the people in our office in Melbourne actually knew that it's Halloween and they've got an "Internet Celebrates Pumpkin Day" booth at the bottom right-hand corner of our innovations page, so you can't accuse us of not being international.

Lastly, I thought probably the other most important reason why people select Planet Internet is that we are renowned for giving the best Christmas parties. And because it's summer for us, last year we did a beach party that degraded into something wet and nasty, but I'm not sure what's planned for us for this year. Thanks very much. (Applause)

Catherine Smith: Not only does he travel far and fast but he also cheats! He didn't tell me he had a T-shirt with him!

As you can see, Joel Maloff is going to be our stagehand. I think if I can get the rest of the gentlemen up here too, maybe they can give him a hand.

We're not going to take a break. We are going to just move the table so that you can get a better shot at all of us and we can go on from there with your questions, and hopefully we'll have all of the answers you're looking for.

Now that I have told you all about their companies, I can tell you a bit about UUNorth as they are setting up. UUNorth does do a 7-by-24 service, we do do dial-up, we do do dedicated services. We do them for individuals as well as for corporations. And while he does Christmas parties in Australia, we do barbecues. And we have barbecues at least five to six times a year, and we've had tremendous turnouts. We find that communications is the most

important thing, and I think that you've gotten all that feedback. Keep asking us questions. Tell us what it is that you're looking for. Because we can't help you unless we know where you're at. So now we look forward to communicating with you further. I'll leave it to Joel.

Joel Maloff: Thank you very much, Catherine. We've got a chair for you. There's another mike over there so you won't need that one.

This is the part of the session that becomes interactive and you are welcome to participate in this. The idea behind this is that for the first time you have the opportunity to have multiple Internet access providers and ask them the questions that you want to know and be able to ask them to answer it. And so I have a series of prepared questions that I am going to start with, but you as the audience are welcome to participate. If you don't like something that somebody has to say, you are welcome to throw out a comment or heckle or other questions. Each of the panelists is also welcome to comment on the other panelists' statements. So again we hope this will be fun and enjoyable but also informative to you.

So let's start with the first question. My first question to all of the panelists, and I will throw this to Mark to begin with since you are down at the end, each of you will have a minute to respond to the question. And, again, you're welcome to respond to each other.

I would like to understand from your Internet service provider, can you define what 24-hour by seven-day-a-week coverage means to you and to your customers?

Mark Fisher: A very good question. 24 by 7 of course in our minds is having an individual available, knowledgeable, capable, to answer a direct call or a live e-mail into our center about problems they have; again, whether this is an individual at home, a consumer, or at work in the business. And we have three tiers of technical support staff set aside; a very sophisticated — as is consistent with our core business — system by which we can track troubles, accept inbound calls, provide on-line help through the Web, through e-mail and through voice response units.

So it is again a very comprehensive solution so that anyone at any time of any day can call us with a problem, we'll help them fix it; with an objective of 90 percent of all problems being handled and resolved by the first person that the customer talks with.

Joel Maloff: Now let me ask the rest of the panel. Do you think the kind of coverage that Mark has described is adequate? (Pause) All of you think it's adequate? Does anyone want to comment? John?

John Curran: Oh, sure. I would like to say that some organizations require a different level of 7 by 24. BBN actually — For those people who don't know the history of BBN, we acquired multiple networks, the networks that were involved in some of the earliest network operations. One of the advantages of that is that we have multiple network operation centers. We run two 7-by-24 network operation centers. We actually operate the network of a number of Internet providers who have outsourced their network management and monitoring to us out of our network operation centers.

And so what we look for is, we look for not only the fact that we have depth of staff, full coverage monitoring the network in multiple locations, but also that the talent that is available and the resources that are available at 2:00 o'clock in the morning for handling our customers' e-mail requests, for handling routine changes, for handling a hard outage, a customer that needs field service dispatch, are just as good at 2:00 a.m. as they are at 10:00 a.m. on a Monday morning. So we run 24-by-7 and that basically means you stop distinguishing between day and night.

Joel Maloff: Alan, do you have a comment as a nationwide provider?

Alan B. Taffel: Yeah, actually I basically thought that Mark had a good answer.

One other point I would make is that while you have different levels of engineers in the organization, it is important that a senior engineer be on hand, on-site, I should say, not at the end of a pager but on-site twenty-four by seven as part of 24-by-7 support. Another point is that the actual network operation center itself needs to be up twenty-four by seven. I know I won't get any disagreement about this point. So it is important that the network operations center itself be on an uninterruptible power supply, ideally backed up with a diesel generator itself, and have plenty of capacity into and out of that NOC.

Joel Maloff: Okay. Now I'll throw it to Catherine and Rael. You both have smaller companies than the other three represented. How do you address the issue of 24-by-7 coverage?

Catherine Smith: We have people on-staff seven days a week twenty-four hours a day. When you pick up the phone and call for help, there's going to be a live body who answers the phone saying "This is UUNorth International. May I help you, please? What is your problem?"

You may have problems and we can help you with your network, but just think if I phoned someone like UUNet Technologies and I say "I believe we may have a problem, could you check your circuit for me?" and I can't get a hold of him. That is not going to be helpful for me trying to get you the best service possible. So we like to work with organizations that do have 24-by-7 support which has actual people, because there's nothing worse than getting a groggy techie who's just piled out of his bed to answer the damn beeper that was across the floor. That's not acceptable. He can't think on his feet and he can't understand what it is you're about. So seven by twenty-four for us insists that we do have an adequate staff all the time.

Rael Kuperholz: Joel, we had to address this and obviously try to make it affordable. And as a startup venture, as a small Internet provider, you don't have the resources of, say, a UUNet or a PacBell. But you can do pretty well. There's certain things that you can do straight-away that can prevent any disaster, things like that you should really be insisting on from me if you're dealing with a smaller Internet provider. And that is, you've got to have redundancy. You've got to have redundant connections if it is ISDN or however you're connecting to the Internet backbone as a provider. You've got to have uninterruptible power supplies and standby power and dual air-conditioning systems and so forth. Things that can certainly bring your network down and are very easily avoidable at a not too high a cost. So we certainly took that approach.

The other thing is using all SNMP- managed equipment, so all the equipment that we use has the ability to be remotely network-managed. And we have managed to interface it very successfully. We use the HP Open-View platform and we use that as part of our network management into our help desk for autoescalation. What that does is, it automatically contacts people if they're not on-site.

Now, we're very fortunate the way we have packaged everything up as far as staff goes in that we've got three of our most senior engineers who can handle the operating system and the hardware all within, if I said three or four minutes from the office, I mean that. But what we do is, we tend to man the office Monday through Saturday through till midnight. Which is the busiest period. Sunday is invariably a bit of a housekeeping day for us so we have people in the office. The biggest issue we have had to face is in fact customer support for the dial-up. And I can understand organizations who don't want to touch it with a barge pole.

We find that supporting the customer on the commercial side is relatively simple. And we also have a deal with the ISDN carriers that we use, and they do monitoring on the lines

and they contact us if there's a problem as soon as they detect it as well. We haven't yet had any downtime of any note, so we're feeling quite relaxed at the moment.

Joel Maloff: It sounds like we don't have much disagreement on 24 by 7. Mark, do you have any further comment?

Mark Fisher: One final comment. Good customer support is good people, good tools, good process. Those are the essential ingredients. I want to add as well that we see an important distinction between what is a 24-by-7 network operations center, which you have to have, and what is a 24-by-7 customer service center. They are two very different organizations. Though they work closely together, they have different objectives. Their success is measured in different ways. And it is an essential commitment to both that nets out as strong customer service.

Joel Maloff: All right. Before I ask another prepared question, are there any questions that you from the audience have? Yes, sir, in the back?

M: I guess my question is to Mr. Fisher but I'll take it from the other panelists as well. How do you see the cable TV industry competing with your business in the next five years?

Joel Maloff: Let me repeat it. The question is, how will the cable TV compete with the businesses that each of you represent over the next five years? And, Mark, he asked you to respond. Why don't you go first.

Mark Fisher: A very good question. The application of on-line services via cable TV connection to the home is an excellent one. One of the reasons why we are committed to building out a hybrid fiber/coax network, a cable TV network throughout the state of California for the customers we serve, in the long run that will take some time to build out. In the shorter run we are pursuing opportunities like wireless cable because we believe, among other things, that the on-line cable TV-based access to the Internet and other on-line and information services is a very good application. We think it is very appropriate to play there.

Joel Maloff: Let me throw it to the other end. Catherine, how will cable TV play in Canada and will your company be put out of business because of cable TV?

Catherine Smith: No, because basically it is not the technology of wire that we are addressing here. We are addressing the matter of services and how we can help you as businesses and individuals access the network.

Cable may be there, cable may be fast, but in Canada we are behind. We are only doing pilot testing now. From what I understand from Rogers as a statement of fact, that they do not believe that the Internet and your PC will actually meet. That you will have your PC and the Internet for business use; you will have the Internet and cable for TV. They do not see it as a combination. So I think we have a ways yet to go in Canada.

Joel Maloff: John, how do you — ? Or, Alan, are you next? Don't be gentlemen; go after it!

Rael Kuperholz: I just want to say something about that, just looking at it from the outside in. Australia is just busy getting cable TV for the first time. We're a bit fortunate in that we don't have the old VHF infrastructure in the ground that you've got here. It's not just Australia. Right

through Southeast Asia they are deploying cable TV. It is the scheme that Mark discussed that is a combination of coax and fiber. We've got multiple carriers committed to spending typically around the six-billion-dollar mark getting up to about 80 percent of the households in the major cities in the next couple of years. And it is something that one has to seriously consider.

I don't think it will necessarily impinge on the corporate usage, but for the home consumer and the SOHO market, the whole philosophy and the thought process in Australia is your Internet access and all your on-line access is going to come via this fiber and this coax. And in one particular carrier's case it is a 10-megabit Ethernet that they are in fact deploying into every house as well as all the cable TV home shopping. So it's something to certainly watch.

Joel Maloff: John?

John Curran: I would like to agree with that. I think we have seen that cable through some of the trials that have gone on in the past and some of the activities going on now will be a very effective, high-bandwidth source for Internet connectivity but it may not be necessarily the platform for the business as much as it is the customer or the consumer market. And the questions that come up from that basis when you have mission-critical applications that we have right now on the network, people who are building their businesses on being on the network, there are certain service levels and service metrics which in the telephony world have been worked over time. And in the cable market there hasn't been a demand for certain response levels, certain monitoring levels. To that extent, it is going to be some time before there is enough demand to warrant that level of service out of the cable plant. I think we'll see very high bandwidth and I think we'll see very cost-effective delivery of service for the consumer market. I am a little skeptical about the penetration into the traditional business marketplace, particularly as businesses reengineer their processes onto the Internet.

Joel Maloff: Alan?

Alan B. Taffel: Well, I'm glad John made that point and I fully agree with it. I guess what we are all agreeing on here, the bottom line is that cable is not going to be competitive with Internet services. We see it as just another way to gain access to the Internet. Today we use many different ways to get access to the Internet, dial, now we have ISDN, which used to stand for an "idea subscribers don't need" and now it actually appears like it may actually do something useful. Frame relay is a good way to get on the Internet, that's a different technology; leased line, SMDS. And cable will be just yet another way that you can get access to the Internet, as will wireless, for example. I agree with John, though, that it is mostly going to be a boon for consumers rather than businesses.

Joel Maloff: Well, since we seem to be agreeing with each other on the panel, let me throw out a more contentious question. I would like each of you to address why you believe your company will be the dominant player either nationally or in your niche eighteen months from now.

In other words, Alan, why is your company going to be the dominant Internet access provider in the United States or in the world eighteen months from now?

Alan B. Taffel: Well, I'm glad you asked that question, Joel!

Joel Maloff: And, by the way, the rest of you can disagree with him.

Alan B. Taffel: And I'm sure they will!

I guess the first thing is we might still be here, since we're actually starting to make money now. We are actually a profitable company now. Which I don't think is a very common scenario in the Internet these days. But the real reason is scale. I think in a word the key to survival in the Internet business, at least it is our belief, is one of achieving significant scale so that you can not only deliver services wherever they need to be delivered and to a large population but you can do so profitably so it becomes a viable business venture. Without scale, that's not possible.

So I believe that our alliance with Microsoft is something that has allowed us to very quickly achieve the scale that is necessary and thus our early profitability. But I also believe that because we are squarely focused on a particular market, which is the corporate market, all we are doing is talking to business customers to understand what their needs are, we will be able to stay ahead of all the other providers with respect to the value-added capabilities and the integration required to make the Internet not just a communication vehicle but to make it an actually useful business tool, to make it the most reliable, to make it the most secure and the most accessible tool possible. That's what we are squarely focused on, and I believe that focus is the key to success.

Joel Maloff: John, why is your company going to beat out Alan's as the most dominant Internet provider in the United States or elsewhere?

John Curran: Well, clearly Alan has touched upon some of the success factors, and they include scale. They include the ability to handle and focus on a particular marketplace. BBN Planet has focused on the business marketplace. We don't serve the consumer marketplace. We are a provider much in the same way as UUNet; we are a provider of technologies, integrations. We built some of the largest networks that exist and we are behind the scenes in many of the consumer services, many of the larger government and military networks, as we have been for twenty-five years.

The good news is that the Internet is changing. Okay? As I sit here, a thousand lines of code are being written during this session and put out on the network somewhere. And that change is a remarkable thing. BBN is actually — The home of BBN is a laboratory. We are an R&D environment where we are watching what's happening in the Internet. We have been involved in the development of all the technologies and figuring out how to use those technologies for business.

As we sit here today, when you ask eighteen months out, I will tell you it's a different Internet. Now, BBN has 1700 people, engineers who are busy working on Internet technologies. As it turns out, Planet, while we may only have three hundred people, we're busy doing the application of that. I am very thankful that a year, year and a half from now we will be able to respond to the needs of some of the largest companies, making sure that they have their Internet solutions that they need, including security, as we've been a leader in before, connectivity, and similar services. That we will be able to address their business needs eighteen months from now, including the needs that we haven't seen or we have only seen in the R&D lab.

Joel Maloff: Mark, let me ask you, what regions do you hope to be able to dominate or areas in the next eighteen months and why will you be able to beat out UUNet or BBN Planet?

Mark Fisher: And of course we are now framing this in terms of the California market. I get to reset the scope of it. But clearly the opportunity we see is not among switching presently connected businesses in California from one provider to another. It is absolutely reaching into the market of businesses who have yet to understand the full value of an Internet connection. And the reasons why we will be successful and a dominant player in that market, no question in my mind, we are a name that customers know and trust and have learned to trust over the last several decades. They understand that the Internet is fundamentally a communication and network service and that that's the core of the business that we're in. We deliver the kind of service and support, our commitment to California, that makes people continue to do business with us. Even as the Internet changes and many other issues around telecom reform and regulation will change, the fact of the matter is we will bring a simple, convenient, affordable solution. It's the one place a customer will need to come, whether consumer or whether a business, to get their basic communication services, their phone line, their data services and their Internet connection.

We want to make that simple and affordable, and with it scale well so that we can reach a very broad base of new customers who are coming onto the net in California.

Alan B. Taffel: Can I comment on that while we're still in the U.S.?

Joel Maloff: Sure.

Alan B. Taffel: I actually don't think it is fair or appropriate to reset the discussion to just California. I mean, it is fine for a company that is just based in California and has no offices outside California to consider a solution, a regional solution like Pacific Bell can offer. But how many companies are there really like that? Why would a company that's got offices all across the country and indeed all across the world want to take on a solution in California that is not extensible? Take on a solution that forces them to go with all of their other offices to look for other providers, all of which have different pricing schemes, all with different billing arrangements and points of contact for service that's going to be a nightmare, et cetera.

I think that for any company that has got a national presence or an international presence, they should look for a provider that can provide a single solution for all of their locations. So that's why I think —

Joel Maloff: Well, that's interesting, but I would like to hear a response from some of the regional providers.

Mark Fisher: A very good point and very well-taken. But, again, the numbers, if you will, 1.4 million businesses in California. Almost 85 percent of those are fairly small to medium-sized businesses who do business in California and have no other sites in other parts of the country that are of direct concern for them in terms of an Internet connection.

I think there are issues with very large companies, the Fortune let's say 2000, and how their Internet needs are met. I think, frankly, for those Fortune 2000 companies headquartered in California, we can meet those needs or at least a good portion of them. But let's face it. The real opportunity is the businesses that have yet to connect. And predominantly we are talking about small, medium-sized businesses, and a regional solution is in California a very good one.

Rael Kuperholz: Just to take that a bit further, I agree with what Mark's arguments and Alan's were, but you can take it one step even broader now. You're only talking United States. I'm involved in a project at the moment for a company that is in the Fortune 1000 for the world,

that One Thousand World List, and they have asked us to cost out and how we would be able to deploy e-mail for them for two and a half thousand offices all around the world. And you come up with a discussion now, you see how you've got UUNet who are largely, your main infrastructure is the whole of North America or United States; you're just in California; I'm in the eastern seaboard of Australia miles away; and BBN throughout America.

Now, what happens in a situation like that where you've got companies like IBM? They'll claim to have a worldwide presence on the net. You've got AT&T Mail, who are pretty widely spread. You've got MCI Mail and you've got MCI common shareholders with British Telecom. And if you look at different parts of Southeast Asia, where I'm sure a lot of American companies have manufacturing plants, and facilities in China and Taiwan, Philippines, Indonesia, and so forth, you will find not one carrier is dominant in all those regions. AT&T is big in India, British Telecom is big in Thailand and Sri Lanka, for example; AT&T aren't there in a big way. So to take that whole question further, what do you do for truly international organizations?

Joel Maloff: Take it!

Alan B. Taffel: Well, just a second. We are going to be in twelve countries outside the U.S. by the end of this year and we will be in over a hundred countries by the end of next year. So what you do for a truly international organization is, use UUNet.

Joel Maloff: You're saying we should wait?

Alan B. Taffel: It's coming very quickly. And, anyway, we have arrangements and alliances with Internet providers and direct connections with Internet providers all over the world more than anybody else that I know of.

Joel Maloff: Wait. We have a comment from the audience. Yes, sir?

M: Is Microsoft going to buy you out and UUNet's going to go away?

Joel Maloff: Is Microsoft going to buy you out and UUNet's going to go away, it's just going to be MSN?

Alan B. Taffel: It is impossible for Microsoft to buy us out, contractually. They own 15 percent of us and there are limitations on how much they can buy. It doesn't get much above that. So, no, there's no way. They have one seat on our board and the board has nine members.

Joel Maloff: I'll walk around down in the audience. If there are other questions you want to throw at these folks, I will be able to pass them on a little better. Anything else you want to throw at them? Yes, sir?

M: I want to ask how specifically having a worldwide solution is going to help these businesses?

Joel Maloff: Okay. The question is specifically, Alan, you've been very big on the fact that a worldwide solution is necessary for businesses. Why?

Alan B. Taffel: Mostly as a matter of convenience, really, so that you have the same user interface at all points in the world. You can have roaming people. There's a lot of international

travel, you would like to be able to dial, for instance, locally wherever you are and still be able to use the same services, your same ID and log-on. Those are some technical sides.

From the business administration side it would be nice to have one billing model that applies worldwide and to in fact have a single bill, if that's what you want, come to the headquarters wherever that may be and then it can be billed back to the individual divisions or whatever. But those kinds of flexibilities, administrative flexibilities, are possible when you have a single provider that has a truly global presence.

Joel Maloff: Now let me throw a question at that. The concern that I immediately have is, not everybody speaks English. What are you going to do about user interfaces for Indonesia or Malaysia or Taiwan? How do you address that? And that's to the whole panel, not just to Alan but anyone who would like to answer.

John Curran: To be fair, you asked a question that started this which is: In eighteen months, how will an Internet provider dominate their market segment? And eighteen months is a long time. I'll just indicate that the Internet is now opening up as a marketplace. As was mentioned earlier by Mark, we have new tiers of businesses entering the market. We also have new channels, new partners. And in many cases you'll find out that as the Internet matures as a marketplace and you see a tier of resellers and OEMs, you will find that they bring the help desk support and some of the scale that is necessary to handle local-language support. So I think we will see a number of answers there. But you have to wait some of the eighteen months to see how the questions work out.

Joel Maloff: Other responses from the panel? Yeah, you have a language problem in your own country, don't you?

Catherine Smith: Well, do we ever! There are organizations out there, there's one called Video On-line which is stating right now that it is in twelve countries with fifteen languages. They are a marketing outfit; they are not a service of Internet provision. They will go to people who are looking to be an Internet service provider and try to sell them a very expensive franchised product stating, well, we've got twelve, fourteen languages, sixteen yet to come. They're not there yet. I don't think any of us are.

The way that we handle our affiliated offices, especially our one in places like Barbados and other outlying areas, is that we take the expertise from the people who are actually out there doing the work in those countries, people who feel comfortable with their service providers or people who want to be service providers in their own current language. It may be Mandarin, it could be Hakka, it could be Haikou. It is not necessary to be the UUNet in London. You could be Jones Internet Service Provider with a UUNet Technologies hookup. In a lot of cases we are finding that you don't have to wear a T-shirt, you don't have to hand out the buttons; you can be who you are, speaking the language of your country, with a good solid feed from an international provider.

Joel Maloff: Go for it.

Alan B. Taffel: I don't think you can be Jones Internet Garage service provider and have a hookup to UUNet. I mean, it does give you a local presence but it doesn't give you the same quality of service. It doesn't give you single point of accountability and that sort of thing.

The important point here is that we are not going to just do this by ourselves and not have local partners. That was John's point and I think it is very important and I want to

reemphasize it. The important thing is to have a common technology across the world specified by one company. Have mechanisms for common billing and have mechanisms for support that doesn't get into a finger-pointing situation between countries, for instance, but still leverages local partners that do speak the language and can provide local support. That's the ideal, that's the best of both worlds, that's what we are intending to do.

Joel Maloff: All right, we have another question from the audience, and the question is: For those of you that are international or planning to expand, especially in Southeast Asia, how do you plan to meet the regulatory constraints in Singapore, Hong Kong, or other countries that have those today?

Rael, you have service in Australia. Are you planning on moving into other Southeast Asian countries?

Rael Kuperholz: Yes. And having done a lot of work in Singapore and Malaysia, we are talking to organizations there already. The only way you can do it is on a joint venture basis. But one just needs to have a lot of patience. It's very expensive and it has to be done as a joint venture. You need local partners to be able to cut through a lot of the red tape and get through a lot of the regulatory issues.

But if you take Malaysia, for example, they take their feeds up largely from Singapore and it is only one carrier and it is fully regulated and it is really up to them to decide what kind of bandwidth they are going to give you. A lot of these countries only have a single 64, maybe 128K line coming in as their total Internet connectivity and it has been largely done for the universities and academia. You have to do it with local partners and tread softly, but there's a huge amount of interest in those countries, an enormous amount of interest. And I think somebody local within each of the countries will certainly realize, well, they are realizing now that there is a substantial amount of money that they could possibly make, and that's going to drive it.

Joel Maloff: Well, you make an interesting point. And for those of the networks that are on the panel that have worldwide designs, how do you intend to address the issue of Singapore or other countries? Alan, Mark, or John?

Alan B. Taffel: Well, yeah, going back to your original question how are we going to address these issues, we talked about countries; the short answer is one at a time. I mean, there's no way around the fact that you've got these regulatory requirements in each country. There are various options in countries that just have various strict requirements. One is to purchase a large Internet provider in that country. That's something that we are in the process of doing. We recently announced that we are acquiring UNIPAM PIPEX, which is the largest Internet provider in Europe and dominates the U.K. Internet market. So that's one approach. The other is as mentioned by the other panelists, that you can joint-venture with a company.

Joel Maloff: So, Alan, from your comments should we assume that you are planning on acquiring a Southeast Asian provider?

Alan B. Taffel: That would be, well, that would be speculation that was well-founded, yeah.

Joel Maloff: You heard it here!

Any other comments from the panel on that particular issue?

Now, to go back to the question we had asked earlier, we've got two, call 'em multinational or national providers and essentially three regional providers. To Catherine or Rael, how do you propose to prevent UUNet or BBN Planet from coming in, taking over your business? They have talked about how they plan on doing it. What are your responses that you think will refute their arguments?

Catherine Smith: We have UUNet Technologies Canada and at this point in time they have come in on a technical basis only. They lack a service commitment. I am still waiting five and a half weeks for their vice president of technology to call me back on a service call that they have yet to have addressed completely.

We deal with people, we deal with individuals, we deal with corporations. I can tell you that I know the name of every single user. I make a point of servicing my customers. I continuously travel to the offices that we have, and we are continuing to build affiliates with good, solid organizational skills. It is not a matter of transport. The transport is going to be with the cable companies, the TV companies, the telcos. And that's fine. Let them have it. We are building services in battlefields that have yet to be discovered publicly. Not that we can tell you about any of those yet and you will see those come up in the emerging six months to a year, I would think.

The key is to be in the battlefield that has not yet been spoken for, not to be flailing around in the one where everyone is at each other's throat.

Joel Maloff: Rael, let me ask you to respond to that.

Rael Kuperholz: Well, just going back to your question, John, Rome wasn't built in a day. And Alan mentioned that you've got to do one thing at a time. It is naive to think that somebody in the United States or somebody out of Europe, Germany, wherever, can just launch into other countries and go in. Having a lot of money or fistful of dollars is not going to succeed for you. It's been tried in all different industries and 99.9 percent of the time it's a horrid failure. You need to partner with local organizations who know the local bureaucracies. They have a reputation that is good amongst local business; they understand the way to work; they understand the culture.

I am quite sure that our help desk operates very, very differently to the way UUNet would. The reasons why people deal with us might be different. Their expectations amongst the customers would be different.

I hear continuously, a good example is, Australians come over or New Zealanders and they can't stand all the interactive voice response and waiting fifteen minutes to be told that number 9 is what you really want, dial 9, and then you get in another queue and then the phone rings out. Things like that that, say, people in the United States might be accustomed to because of the size and the volume of everything. People in Australia consider that pretty ordinary service. So using us as an example, and I've also lived and worked in four different countries and now Integration Design as a company has done installations and worked in eleven or twelve countries now, and it's just been so different, and we've always succeeded because we try and use somebody local.

So I think there's a great place for us in partnering up with, whether it's a UUNet or a PacBell or BBN Planet or anybody. If we do it right now in whatever foreign country it is and we've got the right credibility, we're their ticket to instant success. Their resources, possibly their finances and financial support, coupled with what we have to offer is your recipe for fast-tracking a success plan or a successful implementation.

Joel Maloff: Let me ask, if there are any questions from the audience, we'll take one or two more. Let's go with you, sir.

M: [Inaudible]

Joel Maloff: Okay, the question is for dial-up access or ISDN, for each of your networks, what is the ratio of dial-up or access lines to customers? Do you have one? Is the question clear?

Catherine Smith: The question is clear. The problem is that the answer is a difficult one more than anything else. We can throw ratios up and I've heard a lot of those today and I've heard them for the past months, and that's not something that you can judge. My dial-up customers come in, they may stay an hour, they may only read mail or be in ten minutes. Out of all of the users I have, I can guarantee you that one hundred percent of them are not going to be on-line all the time. So that we keep a number of quiet modems if things get busy and we will turn these up. Usually we know exactly how much usage our modems are getting. We address the issue of busy signals continuously, and we monitor them to be sure we don't have as many busy signals as we'd like. We're a smaller organization, we're far more intense with regards to our monitoring of modems and dial-up facilities.

Joel Maloff: Anybody else? Mark?

Mark Fisher: Again, to answer the question in a way that is traditional for our network purposes, there are design considerations, engineering design considerations like this. Alan had mentioned earlier P01 or P03 or P05, and our actual objectives are in the 99 percent range from an engineering standpoint. But that actually assumes a base of customers that are not yet on board, so we have absolutely overengineered the network in terms of ensuring that anybody who calls in will not get a busy signal. And there are some other interesting tricks, which I'm sure the rest of the panelists are familiar with, you can play when you design the network so that if you do have an overflow situation in one particular local POP, you can forward calls to another POP where there's capacity to take calls. Again, these are the kinds of things that we deal with, capacity planning, arrival times, average session length for folks on-line, on a daily basis. So this is actually at the core of the kind of network we design to serve people well.

Joel Maloff: John?

John Curran: Because BBN Planet has served traditionally the business customer base, we don't offer really dial-up services. Our services are leased line services and they're there all the time, so there is no commitment issue of over-subscription there. We are involved in the network operation of a number of very large dial-up networks. We work with — We're one of the providers of dial-up network services, for example, to AOL. The networks that we engineer there, I can just say, there can be very large ratios of number of customers calling in to number of lines, but that's because of the average customer usage. If you are looking at an on-line service, the average customer usage in hours per month is very different than the business dialing up to get their electronic mail.

So I guess in a particular segment there might be an answer to the question. We don't in and of ourselves offer network services based on dial-up right now, so it's not really applicable. Even then, you should think about trying to phrase it for business customers or consumer or even on-line access, because there's different usage patterns. What seems like a very high over-subscription level may in fact be very low if the average user is only ten hours a week.

Alan B. Taffel: I think that it is clear that there are several classes of business customer that do need dial service, that that is the most appropriate solution for them. In particular, small offices. And that's not to say small businesses. Small offices, which could be branch offices of a very large company. Dial service may indeed be the most appropriate access for them.

As far as the ratios go, I will be happy to answer directly. As you know, we have built this network for kind of two constituencies, one that is using it mostly at night. The dial network, that is, not the leased line network. The dial network, Microsoft people largely use it at night and Microsoft has asked us to engineer that network to a ratio, well, I'm just trying to think right now — I think I'm not allowed to say that number, actually. I'm sorry.

Joel Maloff: Can you give us a range?

John Curran: Positive integer.

Alan B. Taffel: Positive integer! There's a technical guy next to me.

Let me just say, I'm sorry, I was going to give the number but I just realized I probably shouldn't. But I think the actual important number is the peak rate of service, which means the probability that you're going to get a busy signal. That directly tells you the net result. Because the ratio all has to do with your chances of getting a busy signal, so why not just quote that number directly instead of trying to extrapolate it from a ratio.

And we do engineer the network so that there is never more than a 3 percent chance of busy; always less than. That's called a P03 grade of service. And like Mark's network, ours is engineered for millions and millions of Microsoft network users that haven't gone on-line yet and it probably will take quite a while to ramp up, so your chances of getting a busy signal on our network for quite a while is virtually nil.

Joel Maloff: Any other comments from the panel? There was one other question from the audience. Did you have one, sir?

M: [Inaudible]

Joel Maloff: The question is how much capital investment you have. Now, we have five different types of providers with different services, but I think the question is: How much did you have to invest? Are you talking about initially, sir, startup capital or going today?

M: Today.

Joel Maloff: The question is today.

Alan B. Taffel: I can be first because I'll be the quickest. I have no idea. I'm sorry.

Joel Maloff: John, do you have any idea?

John Curran: I guess I have to echo Alan's response. I'm not sure of the right number. I will say we have 25 years of internetworking. And there's a lot of intellectual capital, software rights that come into BBN Planet. So it's a nontrivial number. We use, for example, tools in our network operations center that were developed in BBN for managing very large networks. That is part of the asset base that we bring when we go to operate Internet services.

Joel Maloff: The question is hardware, John, not intellectual. Do you know how much hardware?

John Curran: It's a — I do not know. A very large number.

Joel Maloff: Okay, megabucks. All right, we've got three networks that are smaller or relatively new. Mark, can you comment on the question of how much capital investment you have had to make to get PacBell's service going?

Mark Fisher: No, I can't comment directly on the specific investment for Internet. But I want to say as an indirect way of answering the question, the company's commitment toward advanced communication services, included in that of course is Internet, as well as the cable TV network we are constructing in California is a \$17 billion expenditure which includes capital and expense over the next roughly twelve to fifteen years.

Joel Maloff: Let me address, since Rael and Catherine's networks are smaller, Rael, if you had to estimate today for your network how much capital investment you have, is it a number that you could share with us? And these are Aussie dollars.

Rael Kuperholz: I'll do the conversion from Monopoly money to real money. It's not something that I've really sat down and costed because of Integration Design's involvement. As John said, there is a lot of intellectual property and other actions and tasks and things that have been done by people in Integration Design. But if somebody wanted to go and set out anyway and just start up themselves and buy bandwidth from a UUNet or PacBell, BBN, or whatever and resell and do a decent job, I wouldn't suggest that out of one single city they try to do it with maybe under four, five hundred thousand dollars, and that's U.S.

There are certain basic things you've got to buy and you've got to set up. But a lot of your ongoing costs, a lot of your capital costs are incremental. As you sell more lines, you can incrementally add hardware. But there are certain core things that you need like setting up a help desk and setting up your main routers and setting up your infrastructure and putting your design together and your main news servers and mail servers and Web servers and things like that that you just can't avoid.

Joel Maloff: Catherine, did you have a response to that?

Catherine Smith: [Inaudible]

Joel Maloff: Alan, did you have a final comment on this one?

Alan B. Taffel: Not on this. But I would like a chance to respond to the snipe at UUNet Canada.

Joel Maloff: Sure. Take it.

Alan B. Taffel: Now is okay?

Joel Maloff: Absolutely.

Alan B. Taffel: I just want to clarify this. There is a company in Canada called UUNet Canada. It is not controlled by UUNet. We have a minority interest in that company and unfortunately

they do have the UUNet name. And I would like to agree with Catherine wholeheartedly that the service that this company provides in Canada is awful. And we are in the process of gaining control of that company so that we can either completely revamp it or shut it down.

Joel Maloff: Great. Okay, the — Yes?

M: This is more for Mark. When the United States deregulates, are the RBOCs planning on, the PacBells and stuff, doing anything in the international arena?

Joel Maloff: I think the question is primarily for Mark on this one. With the pending legislation in the United States Congress, when the regional Bell operating companies are relieved of their modified final judgment constraints, do you as Pac Tel and your Internet service plan on going national, international, or otherwise and can you comment on that at this time?

Mark Fisher: Given telecom reform that's pending which we expect certainly will pass in some fashion, we would aggressively move into several areas of business. I didn't know how you wanted to restrict this, but certainly simply long-distance services, interLATA services is core to that. For the Internet it presents us with an interesting opportunity and that is to look elsewhere or out of region, potentially, for providing or expanding the base of influence we have. We will be careful and deliberate about where and how we intend to leverage our California base and our commitment to California elsewhere out of region. In the short run we see California as by itself a very attractive market to serve well right now.

Joel Maloff: Do you think it would be possible, Mark, that you might want to acquire a company like the ones sitting at the table? Can you comment on that?

Mark Fisher: No!

Joel Maloff: All right. I'll take one more question from the audience. Are there any others?

John Curran: Joel, can I comment on Mark's response briefly on deregulation?

Joel Maloff: Yes.

John Curran: Deregulation is going to be wonderful for the Internet because it will enable another class of providers, organizations that have traditionally been local exchange carriers working in a particular area, to now go and provide Internet services. Likewise, it will also open up the Internet because it will enable other companies such as IXC carriers to enter the local markets and do direct access.

In many cases the Internet is suffering; there's places where we have chronic problems which can be tracked down to a particular interexchange carrier, a particular local exchange carrier. And competition will allow us to bypass that and cut around. I actually hope for a more reliable Internet, a more robust Internet as a result.

Catherine Smith: I tell you, in Canada I look for Internet to be in Canada. We don't have very much Internet in Canada because we're so darn big! We are finding that we are waiting for the telephone companies. No offense to Mark. In our case we've got areas that are using cellular and microwave at 9600-baud lines just to use the telephone.

So in Canada, as large as we are, all of our cities are closer to the border so that we are looking to our telephone companies for remote service so that we can actually provide Internet services up in the northern reaches.

Joel Maloff: All right. I am going to bring the session to a close. I would like to thank Mark Fisher from Pacific Bell, Rael Kuperholz from Planet Internet in Australia, John Curran from BBN Planet, Alan Taffel from UUNet Technologies, and Catherine Smith from UUNorth International in Canada. I think they have all done a great job. At this point I don't know that we want to decide a winner. I'd just like to give them all a hand and thank them very much. And thank you very much. I hope this has been useful for you. Have a good day.

(Applause)

INTERNET TECHNICAL AGENTS, DIRECTORIES, METASERVERS...

SPEAKER

Matthew Koll, Ph.D.

President, Personal Library Software

Matthew Koll: Thank you for coming. Speaking of agents, I was thinking about agents trying to start this talk and I was reminded of that very old, bad joke about two guys who are going to be roommates. They were unpacking their bags and one guy has seven socks, one for each day of the week, and the other guy says, "Gee, I have 12."

The point is that more isn't necessarily better, and as my agents — I have a personal news agent on my desk that I've been trying to train for the past several months, and for a while I had it delivering stories whenever something interesting happened in the Web marketplace. After a few days of getting "pinged" every few minutes, I scaled it back and said, "Okay, how about once every four hours," and then I scaled it back to once every day.

So agents are a powerful capability, and we'll talk a little bit more about it as the rest of this talk proceeds. The jokes don't get any better, though.

I'm Matthew Koll from Personal Library Software, and this is my one-man show. We use the words "Personal Library Software" as our company name because the idea is to turn the entire world into your own personal library or have a personal librarian, if you would. Let's just give you about three slides on who we are to keep my board happy and to establish at least some credibility that maybe I have something to say about this subject.

At Personal Library Software, our mission is to bring people and relevant information together. That's a very broad mission, and we do that in really two different ways. We have a long track record of developing and marketing search software.

The latest is a product that we call *PLWeb*, which is an Internet search server that is being used very, very widely on the Web. We also have a long tradition in CD-ROM and enterprise-wide information servers. We've been doing that for about 13 years now.

So, we were doing concept searching, natural language, relevance ranking, relevance feedback and all that stuff before it was cool. The other thing — which I'm not going to talk too much about directly, but is really driving this presentation — is a new project that we've been working on called *At One*.

It is not working yet. You could call it vapor if you like; it's just beginning its pilot phase. And the idea of *At One* is to take advantage of the installed base of *PLWeb* servers and the many people who are doing intelligent searching on the Web — and people who aren't quite on the Web yet — and create a directory, a different kind of guide to where relevant information can be found.

So we'll talk about some of the concepts behind it without going into the products at all, really. And lastly, before we get started, just to give you an idea some of the places our software is, [it's in] some of the most powerful and exciting Web sites such as *Pathfinder* from Time Inc., Time-Warner now. AT&T Net and McKinley's Web sites use our software, and we just announced phillipstock.com. Phillips is a business newsletter publisher, and has a wonderful plethora of newsletters. We just made that announcement yesterday. [They have] *Electronic Newsstand*, *ZIF.com*, *The WELL* and so on. So we have a lot of experience with big databases; I would say we have more experience with big text databases than anybody else in our industry.

So, having thought about concept searching and information retrieval, and relevance ranking and big databases for a long time, I was really excited to get this opportunity to talk about what I think is the next really big issue, which is the idea of directories, agents and meta-searching. How do you figure out where to look?

M: Just a logistical question. Will these five [inaudible] go on your Web site?

Matthew Koll: Sure. Not today, but probably tomorrow. We see ourselves along with many other people as fitting into this vast middle between the users and content.

There are X million Internet users out there, there are X million Web hosts and other content providers. Everybody wants to get their content up on the Web. How do you find that content? This whole entire conference really is a bunch of people trying to figure out how to put users and content together, certainly from the publishing side.

There are other things that people do besides search for information, but from where we come from that's one of the most important things that we think people do. They want information. They don't necessarily want to be searching for information, they just want to find it, they want to have it delivered, they want it to be there. And as middlemen, I think the thing that we don't want is this situation where you build a Web site and they don't come.

Or, you get out there searching the Web and you can't figure out where the information is that you want. According to the popular press — and I think the community by and large, the neophyte community of people who average less than ten hours a week on the Web — that's probably an accurate depiction of the way they feel about things.

For those of us who are spending a little bit more of our life on the Web, we've gotten a little bit used to these primitive tools that we have, but I think we all have a long way to go.

The biggest issue that we have coming up in terms of the content being available on the Web is the issue of scale. I'll show the next couple of slides trying to depict the issue of scale. But I think it's fair to say that in some number, a few years, we'll have several hundred terabytes, several hundred trillion bytes of information all on the Web, all totally connected, all available for intergalactic cross-database searching.

Maybe it's not two years, maybe it's seven years but it will be there. When you hear Larry Ellison or Bill Gates talking about information at your fingertips or the entire world being content-driven, I think that's the kind of volume of information we're talking about. And if we're going to get into the hundreds of terabytes range, how are we going to handle that?

The title that appeared in the proceedings said, "Agents, Directories, Metaservers, Servers, Filters and Scale Save the Day." I don't know where that came from; I think that was somebody being a little bit over optimistic on the copy writing. This is the actual title that I submitted, which was "How Do They Scale?" I'd like to think that they are going to be able to make profound differences in the way we search and find information, but I think we're at the very early days of figuring that out. We just haven't played with data on the magnitudes that we're going to encounter in a few years, so I think it will scale.

I think we've got some really good ideas about how to do it, but it's too early to even say the jury is out. I mean, we haven't even selected the jury.

Putting the question another way, if all the information in the world is at your fingertips, how do you grasp anything? When you have many, many agents sending you information, coming into your in box, more than you can figure out, the next thing you do is have an agent for your agents. And you start having to have an agent to monitor all your different agents that are coming into you.

I have an agent up on America On-line, I have an agent that's in our own office with a mainstream feed that runs against our software, I have other agents that I subscribe to. At some point you're starting to wonder, "How do I deal?" Information overload reappears.

To give you an idea of the magnitude of the data problem and how this just really compounds this experience, that black box represents [in] one year the full text of one or two

years of a newspaper. So a typical newspaper runs about a megabyte a day, maybe a little bit more, so in two years you're talking about maybe a gigabyte worth of text.

A sort-of-major but not huge on-line service such as Dow Jones News Retrieval or Data Times or one of the sort of the second-level in size — not in quality necessarily — on-line services have maybe 200 or 300-500 gigabytes worth of text that they have to search for right now, usually in a dial-up on-line X.25 kind of service — or, if it's available, starting to be available though TCP and starting to be available through the Web. But that's a lot bigger than the one newspaper.

Just for contrast I drew a white square in there to indicate the amount of data that is currently indexed by the most generous accounting that we could give for one of the webcrawler-type of indexes — *Lycos*, *InfoSeek*, *AOL WebCrawler*, these services that let loose a crawler to index all the text that they can find out on the Web.

Generally speaking, the amount of text indexed by those systems ranges between less than one gigabyte to maybe 30 or 40 gigabytes, if we're really generous and optimistic. The largest one I've seen is eight billion pages — and a page is usually 2-5K — with most of them really one million pages or less. So we're talking about just a few gigabytes, a little bit more than the content of one newspaper, for a couple years.

If we now look at a very large on-line service such as Dialog or Lexis-Nexis, Dialog or Lexis-Nexis is about four terabytes, four to five terabytes. Okay, so that really dwarfs everything else. And now, when we start thinking about what happens when Dialog and Lexis-Nexis and university library and everybody's chat groups and discussions and e-mail start getting up there, now we're talking about somewhere over a hundred terabytes.

And the tiny little speck, the green speck is Data Times, the little white square is the amount of index content from the most voracious webcrawler and the little black dot that was just one single newspaper is just about impossible to find.

If you've got all that information at your fingertips... I go back to when I used to teach information retrieval, and I used to ask my students as a final exam the question, "let's assume that you didn't have to worry about processing power or speed. Let's just assume that you had an infinitely fast computer, you have all the information there. How would you decide which document to give the user?"

Because that's really the fundamental question in information retrieval; you've got a user sitting there and the user wants to see. as the next thing he or she looks at, the document that is most likely to satisfy his needs.

How do you pick out that document? What do you do? What do we know from artificial intelligence, what do we know from information retrieval, from pattern recognition, any techniques we apply? Forget about speed, forget about timing, just what could we actually do if we had everything there and could process it?

It's a tough question, because most of the work that is done in information retrieval and database management stumbles on the issue and has to deal with the issue of efficiency. We do things with inverted files and bitmaps and hashing techniques to try and deal with the issue of speed and performance; but I used to like to try to get the students to think about this: what if we didn't have to worry about performance, what if we could just worry about effectiveness?

Well, one of the first things you have to think about in terms of effectiveness is that each word that the user is likely to use to search with occurs millions of times. [that's a] major problem for most information retrieval systems.

Just one of those numbers that floats around in one gigabyte of text — I believe the average word that the user comes to the search systems with, or does a query on, occurs 25,000 times in that one gigabyte of text. So a typical user comes down, sits down, types that

one word, and it occurs 25,000 times and retrieves 15,000 documents. That's a one-word search against one gigabyte.

So yeah, you can do some relevant one-word search, when you don't have an awful lot to work with. What happens now when we have ten gigabytes? Okay, that's 250 million. When you — excuse me, a hundred gigabytes would give us what?

Okay, let's say one terabyte gives us 25 million for the average occurrence. If we get up to the day where we actually have a hundred terabytes, we're talking about 2.5 billion occurrences of a word. So if you start to end up pooling combinations and anything like that, you're talking about identifying hundreds of millions of documents, all that satisfy any query you might come up with.

The upshot of all this is that straightforward indexing methods aren't going to work at that scale. Something else has to be applied. Step back for a second and say, "What are we trying to accomplish in searching for that information?" There are many different kinds of information needs; we're not always looking to find every relevant document.

Sometimes you just want to find any relevant document. "Find me something on the subject," which would be sort of any needle in this haystack. One of the most interesting searches that people do, which will become harder and harder to do, is the one when you say, "make sure there are no needles in this haystack."

How many of you have searched for a patent in a trademark database? You've got a great new name for a product, and you're just praying that you don't find a conflict. Or, if you're a lawyer, [maybe] you're searching and hoping not to find a conflict of interest. Many times we want to have confidence in a negative result of our search; I mean, that's the way I picked up the *Sunday Times* every month, or the *Monday Times* now; *New York Times* on Monday, pick it up, read all that stuff and say, "please don't change my day. Please, did [Mark Offerlewis] not write something that's going to turn the work upside down?"

Looking for needles in haystacks is one thing, but now we've reached the point with many, many terabytes, that the issue is where is the haystack. Which field are we in? How do we even have a clue of where to look? And it is pretty well-established research, that if you look at failures on the major on-line services — and this could be Dialog, America On-line, Prodigy, Dow Jones, any of them — one of the major reasons for people being unsatisfied or failing to find relevant material is they are looking in the wrong databases. They just don't know where to look.

Go back there. Traditional information retrieval methods that have been around since the '60s, since the '50s, are pretty bad if measured in terms of recall and precision, which are the two most widely accepted ways of measuring retrieval performance.

Recall is defined as the number of relevant documents that you actually found out of all the relevant documents that are out there. So if in the universe there exists a thousand documents that you would find relevant, and you found 200 of them in your search, then that's 200 out of 1,000, that's 20% recall.

Precision, on the other hand, measures how much noise you have, how much garbage you have in the set of documents that you retrieve. You retrieve a hundred documents, 50 of them are good, 50 of them are not relevant, that's 50% precision. And generally speaking, in on-line services the sort of ballpark performance that's been seen time after time after time in many, many studies is that a typical user retrieves about 30 to 50 documents, of which about half are relevant and half are non-relevant; but among those relevant documents that they found they usually only got about 20% of the relevant documents that were out there to be found.

This level of performance has been confirmed time after time, in independent studies by many information retrieval researchers. It's one of those things we can talk about why, and you

need to think about why in order to try to do better. [One of the] main reasons why it's so bad is one of overly-prescribed logic. If you're forced to use Boolean logic and phrase operators and things that narrow the search, you tend to force yourself away from lots of interesting and good documents that might very well be relevant; but if you have to go from 600,000 documents down to ten documents for sanity reasons, then you use the tools that are available.

And if the tools are Boolean operators like "ands" and "nots" and phrase operators, well, then you end up missing a lot of things that didn't happen to have the exact language that you thought of to ask your question, but still were highly relevant.

The second reason is that language is just imprecise. [There have been] studies of people asking other people to name objects; you know, what is this? Well, if you ask about 40 people what this is, you get about 38 different answers. It's incredible. But there is great research done at Bell Labs as well as a few other studies, and there is just an incredible inconsistency when people try to name things or to look for things with the names that other people apply to those things.

Now, what's a cup to one person is a glass to another person, which is a water glass to another person, which is just water, a drinking thing [to another], some stuff that you got up there as a twelve year-old would put it. We use different words, and then it's not surprising that you can't find those things that you couldn't figure out how to name. We need more hooks.

One of the things that I've been convinced of over the years of looking in information retrieval research is that the more hooks, the better. If you can use full-text, that's better than an abstract, better than a title; the more words you can expand the word out to, the more you can expand to a concept and find a concept instead of just keywords, the better the chance you have of finding those interesting things that you'd otherwise miss. And last, of course, [you avoid] looking in the wrong place.

So, how do we solve our problem? Well I think there are three main areas where we can make improvements. One is the interaction between the user and the system, and that means the way that we make the request and the kinds of advice that you can give the user. There are things that happen inside the engine, under the hood. How you do the relevance, how you do the concept expansion and then what is called "resource selection," which is where the haystacks problem [comes in]?

This is a very simplified, basic model of what we do whenever we ask an information system for an answer to our question. We start with a query and we pose that query to the system. If the system is intelligent, it does something to that query: it expands it, it spell checks it, it compares it to a thesaurus, it finds some related words through heuristic means. It does something; it tries to improve on the query somewhat.

Over from the other side you have a collection of documents, and you take that collection of documents and we build some kind of document space or index space, or some kind of collected index to those documents. Sometimes I like to call that a "concept space," because it sort of points you to the idea that what you're trying to do is make that concept space somewhat congruous to the concept space that the user has in their head, in the hope that the spaces are the same, [so that] maybe when the person asks the question the documents will be in the right place, the document space.

And then what you do is you compare the query to the document space, and through some matching function "M" — that's the matching function that ranks the documents by virtue of their conformance or similarity to the query.

This is a very general model, but every retrieval system that's out there, even an artificial intelligence, a true AI icon of a knowledge base system, ultimately falls back to that

kind of matching function. You might have slightly more complex matching function, but sooner or later you get down to the point of your matching for the existence of certain strings against the query. It might be an expanded query, it might be fuzzy matches but sooner or later you're comparing string matches to the query string and counting the hits in a more or less intelligent way.

If we introduce the idea of a resource locator or resource identifier or a "where are the haystacks" kind of function, what we do is we take the query, and before we apply it to a specific database or a collection of databases we go ask this thing that I'll call a "meta-search," a "meta-database" or a database of databases. You do this all the time in a less automatic way if you go to say, the *McKinley* and ask it, "I'm looking for some stuff on hotels, where would I go to get reviews of hotels?" If you ask the query it ends up pointing you to a Web site that's got a lot of information about hotels.

Well, you run the query against a metaserver and that metaserver — in this case I'm describing a scenario where the metaserver is, in fact, created from the document collections — so we let the document collections sort of describe themselves to this metaserver, and then the metaserver renders up to the searcher a list of the preferred databases, and then you proceed to go and search those databases. This has the advantage of limiting the search to perhaps a consumable quantity of a few gigabytes as opposed to hundred of terabytes.

Going down a little bit more deeply in terms of the things we can do to make searching better, on the interaction side I have three things: the interaction, the engine processing and then the meta-search.

On the interaction side, I think that first thing that makes systems better is a natural language query. You just can't force anyone outside of the library community to use Boolean logic. If you insisted they use "ands" and "ors" and other kinds of operators you will doom them to asking for things in ways that guarantee that they don't get them right.

On the other hand, if you go strictly with a natural language system and don't provide the user the capability of doing Boolean operators and phrased operators and field restrictions and other kinds of more narrowing kinds of operations, you will also lose lots of relevant documents.

Not to knock any of the existing webcrawlers, but we have a terrible company name, Personal Library Software. It's three common words, and it's strung together. Try going to various of the Web servers, the directory services and do a search on Personal Library Software. About five out of six of them failed dismally. Okay, you got things about library services, you got things about personal agents, all sorts of things, but you don't get stuff on us because they don't have a phrase operator or they don't have a ranking algorithm that takes into account phrases one way or the other. It's very frustrating, and we're trying to fix this.

The third thing is feedback. We are all much better at recognizing things than making them up. So if you can give the user some examples of relevant documents, if they see something on the screen and say, "Find me one like that," that's great. If they see words on the scene and say, "Oh that's a good word, that's a good word," I can take those easily and feed them back into the system and improve the likelihood of getting good results.

The second thing is this whole concept of "advisors," where if it's not just enough to work under the hood, I really think it works better if you interact with the user and give the user a chance to make that kind selection. If you give the user guide the concepts, whether those concepts come from a thesaurus or a web of some sort or if they are generated spontaneously, dynamically — which is a more powerful and certainly complementary technique — but [come up with] ways to give the user the choice and point out when they've made a spelling mistake, point out when there is a related word that they might want to use.

Of course, the problem we all face in trying to offer these higher power tools is to do them in the way that doesn't become so complex that the user doesn't want to use the system. Frequently, we find our Web customers doing a very, very simple "one blank, fill in the blank" search screen and then [moving to] a more advanced, sophisticated search screen for people who actually want to click on it and go to it. So it is a real tricky issue in human interface design to get these more advanced features into the system in an unobtrusive way and let the user ramp up into them.

Okay, with the stuff that goes on inside the engine, several things are really important. Obviously scalability. We're beginning to get to the point where some of the computer operating systems let you have single files bigger than two gigabytes, and that's pretty important, because when you start handling hundreds of gigabytes, if you can only put in a single two-gigabyte file and call it a database, you got a problem. So you have to start getting beyond these two gigabyte limits.

You have to have an adaptability to different environments. If you have a semantic web built for the medical community, that doesn't work real well for automotive parts or real estate. There are adaptive strategies to get a word concept associations out of databases, but I think there are promising and able to be generalized.

And again, as much as possible these things need to be dynamic, meaning that they are done with less human intervention as opposed to more human intervention.

Relevance ranking. Just to go over some of the basics — I hope this isn't old hat to most of you, probably not — but over all the years of information retrieval research there are three things that have come out that actually have a pretty significant impact on relevance ranking. When you're doing a search, whether or not you're using Boolean operators — it doesn't really matter whether or not you're using controlled vocabularies or just the full text, doesn't really matter — but a few things [are important] if you're going to try and identify the relevant documents and bring them closer to the top of the list.

One thing is what we call "IDF," or Inverse Document Frequency, and it's a very simple thing that says, "if the user uses a rare word and a common word, count the documents that have the rare word more importantly than the ones that have the common word." Okay, rare words are more important than common words when a user uses them in a search.

Within document frequency is sort of the obvious point that was made for the first time in 1957, and the principle was this: the appearance of a word in the document, multiple times, is an increasing indicator that the document is probably about the subject of that word. Somebody won a really big prize for that in the late '50s. But you'd be amazed how many retrieval systems are still out there that don't even do that basic thing. And that's just counting the hits, and it does help, but you've got to do it carefully.

We also want to take into account the document length, and what I call "concentration." Concentration and phrases are a pretty similar thing. Basically, when words occur near each other that's a good indicator; if the words are clustered tightly within the document, particularly if the user types in a phrase and the document actually has that same phrase, that's also a good indicator of likely relevance. But again, I stress this as a behavioral problem; this is not a computer science problem, this is not amenable to some theoretical proof, this is a question of does it work better.

I want to make sure that we're covering the bases, and since we're talking about agents and directories, metaservers etc., I just want go through some boring definitions and just try and clear the air with some of these things to make sure we're all talking about the same things.

First pet peeve; *Yahoo* is not a search engine, please. The folks at *Yahoo* would like you to get that straight, too. *Yahoo* is a directory service, like your telephone book. A search engine

is what PLS sells and Fulcrum sells, it's the thing that does searches, that goes inside of an application and lets the application have powerful full-text access. That is a search engine.

And I'm going to try, for the remainder of 1995, to fight that battle and get people [to call] those things search engines and those things directories. A search system is bigger than a search engine. Our *PLWeb* product, the *Netscape Publishing System*, those are search systems, much like a DBMS is a system. These are search systems; it's more than just the engine. It includes human interface code, it includes database loading processes, it includes update procedures, it includes document filters for getting things in and out of the database — there's a lot more there than calling it a search engine. The engine is the core of the little engine part, but the search system has a lot more to it.

A search service — I would call something like a Dialog or Dow Jones a search service. Okay, so *InfoSeek* is a search service and it's a directory service. Make a distinction between information retrieval systems and document management systems. DBMSs such as Oracle are introducing text handling, Informex and so on are introducing text handling, but there is a fundamental difference between the way DBMSs and text retrieval systems go about finding relevant information. There are technical differences in the way you do the file structures, there are operational differences in the way that you figure out if the results are good or not.

There are some fundamental differences there, and people have been trying to marry the two for a long time. We're in there pitching ourselves; we have announced a deal with [Alustra], who has some of what they call "object-oriented" relational technology. And we've integrated our text searching with their DBMS, and there is some powerful combinations there such as Oracle and other folks are doing [things], but they are different.

For example, one of the other things I'll try and cover a little bit is standards. SQL is a terrible way to look for information. SQL works really well for a structured query against a database; if you're trying to search for concepts within some huge collection, SQL is a disastrous mistake. So you don't want to use that language to do an interactive search, where you're trying to find relevant information.

Again, with an information base versus a database, we're talking about the issue of degree of structure. That's really what it is; a database tends to be highly structured and has many updates and transactions against it as there's searching, whereas in an information base we tend to be thinking more of the one publisher/many consumers, and the most general access is people searching for something as opposed to getting records out to generate reports. So it's different kind of structures.

Full-text index. Just to make it clear, most of the products on the market do in fact index every word within the document. I mean, you can use it if you want to, but that's really an option for most of the systems now. So, full-text means that everything that's there is searchable.

Concept searching is worth spending a little bit of time on just because it's beginning to be really bandied about as an abused term. I'll throw out my definition, but to me concept searching means the ability to retrieve documents that didn't contain any of the words that you thought would be relevant. And further than that, it's done without any human being having to have created that. No human being should have had to tell the system that this word is related to that word. The user shouldn't have said, "here are the words."

To me, true concept searching is when the system is able to figure out that this word should go and get mapped to a bunch of concepts — which of course get translated into a bunch of strings — and will find the documents that have those strings and show them to the user and rank them, even if they weren't any of the words that the user knew about.

To me that's the most interesting and fun part of being in information retrieval, being able to find things that you actually find relevant, but you really would have never done it any

other way. You wouldn't have specified these words; you would have never thought that these words were the right ones to look with. In a Web server — if you don't know what a Web server is, I don't know what you've been doing here the last couple of days.

"Metaserver" is some terminology that we're starting to coin in terms of something that figures out where the haystacks are. The word, the prefix "meta," has been used for a long time in the data models world to mean things that describe some other things themselves — so meta-data is data about data. So when we talk about a metaserver, we're talking about a server that guides you to other servers.

Webcrawler indexes, this is important. There really are — I said I'd talk about directories — I think there are three kind of directories that we should care about. There is one kind which is the human editorial-based directory, and examples would be *McKinley*, *Yahoo*, *GNN*, human beings sitting down and deciding that "here's a good description of a Web site, and if you ask me the right questions I'll point you to some good places."

A second type of directory that exists now on the Web are things like the *Lycos* webcrawler that has essentially a webcrawler or worm or wanderer or whatever you call it, which is something that goes around the Web and sends the text back to a central location or sends an abstraction of the text, but mostly sends cross-text, and then you build a central index like a regular text retrieval, a full-text index residing on the central server to all those locations.

That's what you have on *InfoSeek*, and that's sort of become a pretty popular thing. We now have four, five, six of these in operation. There seem to be new webcrawler-style indexes to the Web forming daily, and they're now up to indexing maybe a million pages — or in one case, eight million pages worth — of text out on the Web. The reason why I think that the third form, which is the metaserver, is required is because of where the content is.

If you remember back to those pictures, if there are only one to eight million Web pages lying around there, that's not a lot of data compared to all the rest of the data. Most of the rest of the data, though, is behind firewalls, it's behind subscription log-in accounts that you have to get to, it's inside structured databases or text retrieval databases where the owner of that content wants to control the access to it.

They're not — Dow Jones isn't sitting there leaving three hundred gigabytes around where anybody can get to it whenever they want. A typical example would be one of our customers, a small on-line service in New York, [*Home BaseLine*], that has some good number of megabytes, probably hundreds of megabytes of text all organized into databases, and if you subscribe to it you can log on and you can search, hit, and you can pay by the piece. But what a webcrawler sees, if you get onto any of the webcrawlers and do a search on the baseline service, if you type in "baseline" what you find is the two, three or so pages that are invisible above the firewall, the tip of the iceberg if you would. So a webcrawler can scratch the surface and they can even dig down deep in the publicly available areas, but they can't get into the real meaty content because content owners aren't about to just leave that stuff out there.

[Tape change]

Matthew Koll: Interactive search base versus agent in profile, can I contrast those? Sometimes I'm prone to say that an agent is just a query on the timer, that's only a little bit of an overstatement. You know, we used to call it "remote job entry" or "batch processing." Basically, there are two ways of doing the searches; you're either engaged in the process or you sent the messenger out to do it. And what an agent is a query or search that you've created, and you tell this agent "keep operating after I've dispatched you. Go out there and run everyday, run every hour, run on demand. Run on whatever schedule I can have you work and send me back the results." Really, at this point, that's what an agent is.

We think there is more progress that can be made there, and we'll get into that in a second. One distinction I would like to stress here — and this is something that I think is important in terms of scalability and survivability of the technologies into the next generation — is the issue of automatic versus manual.

And I think that's been a theme that's been running through this talk to the extent that there's been any theme. Automatic means that you don't have to do the labor-intensive things to make the thing work. Okay, manual things, such as human indexing, is a good thing if you've got it — if you can pay the labor. Semantic Webs, great, [but only] if you can pay the labor.

Okay, "whole cogent" models; if they're automatic they're much more impressive to me than if their manual, to the point that — without getting bogged down in the whole theoretical discussion now, but this does get down to a whole right brain/left brain, theorists versus empirical scientist, one side versus the other.

You got guys over here who have gone through classical computer science education, logic and theory, and you've got guys over here who have gone through behavioral science education, psychology and flight control, a great area — one of the things that I think has a profound impact on where this whole meta-searching and meta-navigation thing is going is the research on human factors, for pilots and folks like that who have to consume tons of information quickly. Because that's what we're trying to do, we're trying to figure it out — we got lots of documents out there, which ones might be relevant? So the whole issue of multidimensional display and how you parse through that very quickly visually is something that finally is coming of age.

Again, you know, the left side is — not that those are worthless tools, it's just that those are tools that tend to be a bit more manual-intensive, and the right-hand side tends to be the tools that are what I would call "emergent," and can arise on their own.

So, for example, classification versus dynamic clustering. Okay, it's one thing for a bunch of librarians to try and classify stories as they come in; it's another thing for a user to be able get on this system and just say "well, organize these for me."

Just to give you an idea of some of the concepts of distributed search, [let's move] right ahead here to a rather complex-looking diagram of a distributed search.

Talking about distributed searching, what that really means is if you look at just what's inside that square — and this is our product, but it could be other people's products as well — you have a browser connected to an instance of a search system, and that search system points to an index, one or more indexes — which is the little circle and that index points to a bunch of disks, hard disks, CD-ROM disks and so on. Your basic search system.

When we talk about distributed searching, what we're talking about is more than having text that's in other locations. Having text in other locations that you index in one place is good, that's an important thing, but the next big step and this has been taken by ourselves and some other companies this year, is to have full distributed indexing where you have multiple indexes in different places.

Different databases gather around the Web, and you can do one search that simultaneously, in parallel, searches with those other things and then combines the results into one merged, unified, relevance-ranked result. That is existing shipping technology — that's not vapor, it's not next year. That's real technology, and you can do that. In fact, anyone out there who has our *PLWeb* product can cut a deal with anybody else who has the *PLWeb* product and can make their databases look like they were one database to any users that you want to.

The reason I like the fully distributed model is that the distributed model also gives you sort of this "bottom up" approach to letting the administrator at the site do what they have to do to manage their own site. You're not waiting for some webcrawler to come and take over;

the administrator is in control of his or her own site, you get parallel searching and you get the maximum flexibility between having indexes locally and having indexes remotely.

The idea that the metaserver then introduced into this picture is that the metaserver says, “well, here’s a bunch of different databases out there, on different Web servers, ask the metaserver which ones are most likely to contain relevant information and then go back and do the search against those local databases.” So again, it’s a different concept from a webcrawler, and I think that metasearching — here we show the metaserver in the center of the picture as a master traffic cop, if you will, going back to the user and saying, “you know, look here, look here, look here.”

So the vision is to unite all the databases. Let’s embrace this hundred terabytes and say, “Okay, we’re going to get them all together, we’re going to organize it dynamically on the fly with minimal effort. We’re going to let it organize itself bottom up and let the content describe itself.”

Another great principle from the ‘50s is the basic principle in advanced information retrieval, [and that] is that the data can describe themselves, that the language in documents is really rich and you’ve just got to use a little statistics, a little bit of parsing perhaps, a little bit of stuff to tease it out and let the user interact with it. I think the methods are here, and when I say searching that could be an agent that’s searching as well as an interactive search. But advance searching — meaning natural language concept capability, relevance feedback capability, clustering capability and distributed searching — is absolutely vital if you’re going to have scalability.

Metasearching [is important] because you can’t look everywhere all the time [with] browsing recognition and interaction. Those features are where I think the true leaps are going to be. As much as I love information retrieval engines, I think the real innovations are going to be on the representation and browsing sites, so that you can just [inaudible] more about what these things are faster.

To jump ahead then to sort of review — we’ll have a quiz on the definitions at the end, they’re passing out blue books — I think that over the next few years there is going to be growth, and I’m going to call these “emergent” methods. So the non-deterministic, the ability to cluster dynamically to find words dynamically — I think that will start to prevail, these associative techniques, because they scale more easily. Multi-dimensional content representation is absolutely vital.

We finally have the bandwidth, we finally have the terminal, we finally have screens that we use. Some things that are more interesting; it’s a lot of research that was bubbling around ten, fifteen years ago, that a lot of UI guys just wish they could get out to the public. I think it’s finally going to start to come out now in the next few years.

And, of course, personalization. I mean, that is what agents are all about.

Agents are about getting your personal preferences in there, and it’s not just necessarily the words you like or the words that you put into your query. I do think an intelligent agent... To be intelligent, one of the things that I would say marks an intelligent agent is the ability to suggest new words to you, the ability to suggest words to add to your profile or delete from your profile that you wouldn’t have thought of. I think as we get into personalization of agents there will be lots of little things where you say, “Well, I don’t like this publication, I do like that publication,” and lots of little fine specific hand-tuning, but also the conceptual fine-tuning that comes from sensing which words work better for you.

I think I’m just about out of time, so I’ll leave it at that point, and it gives us about five minutes or so for questions. I’d be glad to entertain any.

M: How much thought have you given to [inaudible] different vendors searching? [inaudible].

Matthew Koll: Probably about an equal amount of thought and talking, which is a little. There have been some discussions. There has been some, a little bit of movement and it's conceivable that we'll make some progress in '96 on that.

M: I noticed when I use search engines that I'm offering a different person depending on the purpose of that search, and I'm wondering why there aren't more features that simply allow me to qualify myself as a novice or a professional in any particular search.

Matthew Koll: Why there aren't more? I think just because UI developers are overworked and laboring, like everybody else right now in this industry. It's a little bit hard to do. I think most people recognize that it's important to do. I would say one really good example, to plug another one of our customers, America On-line, I thought, did a really good job implementing the on-line database.

It's a Web database, but it's strictly on AOL service, so you just can't get there though the Web. But they have three different levels of interface — you know, simple user, moderate level of sophistication, and sort of heavy duty complex, and I think the AT&T site does that as well. I think we're starting to see more of it, it just takes a little bit more thought and care to do it that way.

M: [inaudible]

Matthew Koll: Well, I think what most of us do is that we search on words, and I think words are a pretty good thing to work on. You can search on arbitrary bits, strings, and there certainly is pattern recognition technology of the fingerprint variety that is good for searching generic patterns. And that stuff can be pretty impressive in terms of matching pictures and things like that.

I don't think the results indicate that is actually better for searching for words than the word search methods, because the word search methods actually get to take advantage of phonemes and things like that. Generally speaking, we just support abstract documents, HTML documents linked to anything [inaudible] documents, Acrobat documents. Links are links, and we're not really — we're just sort of ignoring them.

M: What does source [inaudible] keep up with this technology?

Matthew Koll: Certain [inaudible] says of information retrieval that the best source is the ACM special interest group on information retrieval, [SIG IR], which has manual conference proceedings and a newsletter. And really, in the popular press it's kind of difficult, it doesn't get covered in too much detail as [much as] maybe that's appropriate.

But there are some publications that go into it from the librarian's point of view, like *Searcher Magazine* and things like that, *On-line Magazine*. They occasionally will have articles that go into the searching and indexing capabilities, and every now and then there's a review in one of the PC magazines or something like that. But I think [SIG IR] is the best.

M: I noticed that there weren't any [inaudible] conference on searching, how you search.

Matthew Koll: I think most of the books that I'm aware of on on-line searching are really targeted towards librarians learning to use the older style on-line services. I can't think of anything. We've actually been trying to put some stuff up on some of our customer sites to

help make the help easier than just “well, try this and try that,” and hopefully it’s gotten easier to the point that you don’t need the full books on it.

You know, there are books on using *Excel*. I mean, I suppose there should be some books on that for language searching and using advanced search methods, but I’m not aware of any at this point.

M: What about [inaudible] if you want to dovetail? You know what I mean, that’s where you begin to searching words a certain way and [inaudible] Web site on traffic but you get Microsoft and a different text [inaudible].

Matthew Koll: Right. I don’t know. Somebody else did that? I thought we were the only ones. I don’t know. We’ve certainly given that some thought. I know it used to be a thing with authors, certainly in the information retrieval area, authors of research articles have been kind of sensitive to this for years. You know, you put words in the title and the abstract to make sure that when people are searching they find your thing.

M: Aware of how [inaudible] key?

Matthew Koll: I suppose it’s one of those things — with the camera being on you, the observer changes the thing — and I suppose that might be a good thing. Maybe if we’re a little bit conscious of the language we’re using, because somebody might be looking for this later on, so we’ll provide a few better bread crumbs for actually finding it. There’s a silver lining perhaps.

M: [inaudible]

Matthew Koll: Great. The statement was “Or you get in a rut and can’t think about things in new ways in which you still defy the language.” I guess I wouldn’t worry too much about that at this point. Yeah. Last question.

M: Did you see any [inaudible] point on the development search wizard and stuff like that?

Matthew Koll: I’m not privy to what their doing in Redmond on that. I would certainly think so; I don’t see why not. I think all of us could do a better job of help and advice and taking people through the steps. Absolutely.

Okay, well, I’d like to thank you very much. Oh, I should give you a plug for our booth. We are exhibiting down in 837, I believe. So you’re all welcome to stop by and harass our staff and tell them, tell them I sent you. Thanks.

INTERNET TECHNICAL PGP: ENVELOPES FOR YOUR E-MAIL

SPEAKER

Braddlee, Ph.D.

Network Information Consultant, NevadaNet

Braddlee: Good Morning. There are two handouts that are going to be circulating around. One is a reprint of an interview with Phil Zimmerman from Internet World from August, and the other is a four page handout of WorldWide Web resources on PGP and encryption. It's basically a list of URLs organized by category. So there are 100 copies of those, so if you don't get one and you would like one later, please feel free to come up and give me a business card. Also, both the resource list and the overheads will be available at the Web site listed at the bottom of the opening screen here.

And I guess we'll get started. My name is Braddlee. I am the Network Information Consultant for NevadaNet, which is the University of Nevada's Higher Education, NSF-sponsored, statewide mid-level Internet network for the state of Nevada. This talk is going to be on Pretty Good Privacy, or PGP. It was originally billed as Privacy-Enhanced Mail, although I would like to clarify something. PEM, or Privacy-Enhanced Mail is an official Internet standard which is actually different and separate from PGP. PGP does not conform to a number of the standards for [inaudible] and PEM products. And it is actually a little different, and we're going to talk about some of those differences as we go along.

So the talk is now titled "PGP: Envelopes for Your E-mail." My e-mail address is on the screen there. Please feel free to use that. And once again, both the handouts and a copy of the presentation materials will be available at the Web site, which is <http://www.scs.unr.edu/cs/pgpresources.html> — that's for those of you listening on tape later.

The first thing I'd like to cover is the all-important question: "Do you want to be here?" This is basically a general introduction to public key cryptography and PGP. This is not a technical discussion. We're not going to be going into the details of whether IDEA or Triple DES is better for the conventional encryption of files; that's not really the focus of what we're trying to do. This is a very general and non-technical introduction intended for novices, people who have maybe read a little bit about PGP in the newspaper or in magazines and want to know more about it, want to have an idea of how to use it, what it is and how to get it. So hopefully you're in the right place.

We're also going to address some of the current legal issues and concerns that are going on, both about PGP specifically and about the larger issue of encryption in general.

Okay. So, the questions that are going to be addressed: What is PGP? What is Pretty Good Privacy? What is the nature of the software, where does it come from? What does it do, and why do you care? What does it do at the level of, basically, how does it work? And why would you want to use it? What are the basic mechanics of public key encryption, and how does PGP work as a hybrid example of that? Where does it come from? Where can I get it, on the Net or from a commercial vendor? How do you use it? Is it legal? Is it legal to use PGP, and in what ways is it legal or not legal? Is it secure? Will it actually protect my files? And how do I get help with it if I need help?

PGP is a software package. It allows the secure exchange of e-mail, it allows the attachment of digital signatures to files and it allows the protection of files, for example on an individual computer. To back up just a second, how many of you folks are business users? How many of you folks are business people? Okay. How many of you are education? Okay. How many of you are government? Okay. I've been coming to Internet World for about the last

three or four times now, and each time when I ask that question the ratio of business people goes up and the ratio of other users is going down, which I think is kind of interesting.

Something that you ought to know as far as using PGP for commercial use — and we'll get into this a little bit more in a couple of minutes — but the RSA, the encryption libraries for public key cryptography that are used in PGP, are licensed for non-commercial use only. There is a publicly available product which is a commercial version of PGP called "Viacrypt PGP," and we'll talk about how you can get that. Most of the things I'm going to be talking about as far as this context are going to apply to Viacrypt PGP. The differences between the two packages are essentially having to do with the licensing; so for you guys, when I say PGP you can either think about it in the context of using it for your own personal stuff, or you can just put in Viacrypt PGP and everything in it will be the same, it will be applicable with the exception of version numbers.

PGP uses a hybrid of public key and conventional encryption. We'll talk a little bit about what public key encryption is and what conventional encryption is, and how PGP works as a combination of the two. People sometimes get surprised when they find out that PGP doesn't just use RSA, the public key encryption algorithm for encrypting documents or encrypting e-mail. It actually is a hybrid; it uses both RSA, which is the public key cryptography, and IDEA, which is I-D-E-A, which is a European-developed conventional encryption scheme. And we'll talk about why in a couple of minutes.

Again, RSA is the public key encryption. I-D-E-A, IDEA, is the conventional encryption, and MD-5 is the third element in here. MD-5 gets used for digital signatures, and it's a one-way hash function. Basically you think of it as "things go in, but they don't come out easily." It's a secure message digest function, somewhat analogous to a checksum.

A little about the history of PGP; PGP is written by Phil Zimmermann. He wrote the first version pretty much on his own, but now there's a development team which includes a number of volunteers worldwide — although the versions that are released from MIT and the people that are working on it there, because of the export concerns and export restrictions on cryptographic software, are U.S. and Canada-based. Phil was a software programmer, and he had an amateur interest in cryptography that just basically grew. It grew out of a concern for privacy and what the environment is like when cryptography is not available to people, and what the current on-line environment represents in terms of needing new tools and needing new ways to protect and secure privacy.

If you go downstairs there is a lot of talk about gathering data about individuals for marketing purposes or other purposes. And I certainly don't have any objection to that; I used to work for a commercial survey research firm, so it's not at all that I'm anti-business. But there is a balance between people having a right to privacy in their communications and a right to protect their identity, or even to anonymity in certain contexts, and the legitimate rights of marketers to collect data and information about their customers and to use that — the questions about who has rights to information about individuals.

Phil basically threw Version 1.0 of PGP over the wall in 1991. It was hastily finished and not really a complete product. The reason he did that was that there was legislation going through Congress at the time which looked as though it was going to possibly outlaw all public key cryptography, and he basically wanted to get the package out before that legislation was passed. It did not pass, however, there are a number of continuing concerns in this area.

Version 1.0 of PGP did use RSA as a public key encryption engine, and it also used for the conventional encryption something called [Basamatic], which Phil had developed on his own. There are a number of problems with Version 1.0. One, and the most serious one as far as most people were concerned, was the licensing. At the time Version 1.0 came out I was a co-sysop for the Electronic Frontier Foundation as a volunteer on CompuServe, and we had to

pull, at that point, the early version of PGP off of CompuServe because of the licensing concerns and the patent restrictions on the RSA encryption algorithms. RSA is patented, and the license and the rights are owned by Public Key Partners. The early versions were basically — there's some dispute about this — but the early versions were basically in violation of some of the patents, the patented rights of the holders.

[Basamatic], which was the conventional key encryption scheme, was not a particularly good one; so shortly after Version 1.0 came out, Version 2.0 came out and used IDEA as the conventional encryption engine. And basically the versions through 2.3a are sort of the pirated or outlawed versions. I don't want to put too strong a tone on that, but basically they were not necessarily legal and legitimate. There was a significant dispute about that.

However, from Version 2.5 on, PGP uses the RSA 2.0 libraries, which are licensed for non-commercial use. And it's been distributed through MIT, and in Version 2.6 and above there are no real legal questions as far as the rights to RSA and the software that's being used inside PGP. So if you're concerned about being street-legal and legitimate, from the perspective of being able to use the software domestically, then if you're using a Version 2.6 and above you're fine. The current version distributed in the U.S., through MIT, is 2.6.2. Okay? So if you get the current version from MIT you're okay. Yes?

M: [inaudible]

Braddlee: Yes. We'll talk in a second about Viacrypt and how you can get Viacrypt products. But yeah, there is going to continue to be that non-commercial restriction on all the versions that come out of MIT. I would suspect that would be now and in the future, until the patents expire. The patents expire on RSA in 1997.

Okay. Why do you care? Why would you want to use PGP? Beyond the sort of fun, recreational, secret decoder ring kind of aspects of this, there are a lot of changes that are taking place in our society that are being brought about by the widespread dissemination and adoption of information technologies. The Internet and the Web is only one example of this, but it's certainly one of the foremost ones.

A lot of people, and even people that I speak to in higher education who I would assume would be kind of informed on this at this point, are not really aware of the lack of privacy and the lack of security with most conventional e-mail, particularly Internet e-mail. Internet e-mail — you've probably heard this before, but it can be likened to sending all of your e-mail on a postcard, and you don't have an envelope. E-mail is essentially a text file with some header information that tells it where to go and where it's coming from, and the path it's taking to get there.

So one of the things that PGP allows you to do, and probably one of the most important ones, is that it allows you to have an envelope for your e-mail. It allows you to make sure that the electronic message that you're delivering is readable only by the person that you intend for it to reach.

Now, what are some of the ways that this can go astray? Some of the ways that this can go astray are simple human error. I have an unusual name; it's Braddlee, and it's spelled with two D's. People all the time are calling me and saying, "You're e-mail is broken." And my first question is, "How did you spell my user name?" And they'll almost invariably say, "B-R-A-D-L-E-E." And I say, "Well, it's B-R-A-D-D-L-E-E." Now, if you're sending me e-mail and you do it with one D and not two D's, it's going to bounce, and when it bounces a copy comes back to you. But a copy also is going to go to the System Administrator for your site. And that's a perfectly legitimate thing to have happen, because a System Administrator needs to know and understand what's going on with mail. And if you have an intelligent, responsible System

Administrator, like most of us do, that person is much too busy to do things like read your e-mail. But you can't presume that's the case.

And you may have a responsibility to other people. In higher-ed, one of the things that I'm seeing more and more frequently is that researchers are exchanging data sets over the Internet, either by electronic mail as MIME attachments or by FTP. One of my concerns about that is when it contains sensitive data about individuals. As a researcher you have a responsibility to protect the confidentiality and the identity of the people that you're working with, the people that you're doing research on. If you have someone and you say, "Jane Doe is a lesbian, she drinks more than 24 drinks a day and she is more than \$100,000 in debt," aside from Jane being in pretty rough shape that is information that you don't have any right to handle carelessly. PGP is a tool that will allow you to keep that information confidential and make sure that it doesn't get to anybody that it's supposed to not get to.

Basically, you want to use it when it's a case in something where it's nobody's business. For instance, two weeks ago I was in the process of negotiating for a new job, and the people I was working with down on campus, we were exchanging salary things back and forth; and there was no way that I was going to do that over e-mail, just because it was nobody's business. And the people that I was working with do not use PGP, so I was not able to have a secure transaction with them by e-mail.

Another example is if, in fact, it is somebody's business, like if somebody wants to find out what it is that you're up to for competitor intelligence, that type of thing. You know, I'm not particularly libertarian in my orientation, and I don't necessarily believe that the government has no role in the rights of individuals. A lot of people that are involved in this area do take that perspective. But I think that you have a right to assert your right to privacy.

When I see things, for example, on a Web site... The day before yesterday a posting came up from the Federal Register that the FBI, in the follow-through from the digital telephone proposal that passed last year, has proposed that they will be tapping and monitoring up to 1% of all the phone calls in certain selected geographic areas of the country. My guess is that probably means Miami's Dade County. I live in Reno, Nevada. Reno, Nevada is not really what you'd call a hotbed of organized crime or drug trafficking. But the thing is, is that you do still have, at least at this point, a right to use these tools, and it is probably a good idea to use them and make a pattern of using of them, and to help other people make a pattern of using them so that it becomes accepted as the standard and the norm that you do have a right and expectation to privacy.

[There are also] other sort of security risks. In addition to having bounced mail you can also have a situation where people are deliberately tapping in to the line. It is very easy on TCP/IP networks to follow the data stream, to put a sniffer on the network to watch the traffic going by. You can't just snatch any package out of the air anywhere on the Internet, but particularly in a local area network it's fairly easy to monitor and follow traffic.

How does PGP work? PGP uses a combination of conventional encryption and public key encryption. Now, this is probably the area in which we may lose some folks, I hope we'll avoid doing this. You can think of conventional encryption basically as working like a combination safe; you can put something in, lock it, and spin the knob, and if somebody else knows the combination they can come in and take it out. So if you have a pass-phrase, let's say, "The king is a fink," you give that pass-phrase to your friend Alice and then both you and Alice can get into the safe and decrypt the message.

Now, that works fine as long as there are just two of you that want to exchange messages, and as long as you're not ever going to have to change the key, as long as you're not ever going to have to change that pass-phrase, that key to decrypt the message. Because one of the problems with using conventional encryption is, how do I get you my key? If we're in the

same room I can give it to you; but if we're not in the same room I certainly don't want to e-mail it to you. I don't necessarily want to give it to you over the telephone.

And the problem is that if you have a group of people, all of whom want to be able to share information back and forth, you don't necessarily want to have everybody in that group all using the same pass-phrase, all using the same key. If they're all using the same key, then if one person's key is compromised the key of everybody in the group is compromised. So then you have problems with groups of users; you have problems with key exchange. But basically it's the simplest form, and that's been fairly conventional up until recently about how to do this kind of work.

Public key encryption, which became available first in 1977, was patented in 1977. It allows you to give away public keys, and you should think of the public key as having kind of a one-way function. I or you can give that public key to anybody. I can hand it out to each of you, I can put it up on the screen here, I can write it on the wall of the bathroom here in the airport or in Las Vegas. It's okay, it's not a problem, and I don't have to pay any attention to the security of my public key as far as distributing it to other people. The function of a public key allows me to have other people send me messages, which then I can decrypt with my secret key. The secret key I keep secure; I don't hand it out and I have a pass-phrase that's not written down anywhere. That's what I use to decrypt the messages to other people, and also to sign documents. Okay.

In public key cryptography you also have some key management concerns as far as distributing keys. How many of you are familiar with the government's "Clipper Chip" proposal? Okay. In the Clipper, which is for voice telephone rather than for electronic mail or for documents, public key management is handled through a key escrow system in which the government keeps each half of the key, and the only people that can listen in on your telephone conversations are you, the person you're talking to and the Government, if they have a court order — or if the system isn't broken.

There are problems with authenticating keys. I can have a key, a public key that says it's from Bill Clinton, but I need a way to be able to verify that. One of the things that PGP does is use key fingerprints, which means that I can use that key fingerprint. For example, if it's on my business card or if someone reads me their key fingerprints that they have for me back over the phone, and we both have a reasonable level of trust that we're talking to the right people, we can do that. So that's a way to authenticate the key.

One of the big problems with public key cryptography in the PGP model is in terms of revoking keys. If someone is looking over my shoulder as I'm typing in my pass-phrase, or if I have some other reasons to believe that my secret key has been compromised, I need to have a mechanism for revoking keys. PGP, at this point in time, doesn't do a great job of this; and that's because PGP has chosen to work with a very non-hierarchical system of key management, which is basically called the "Web of Trust."

One of the ways that you can also help to authenticate keys is by signing a key. If this gentleman down here gives me his public key, I know him and I can sign his public key and say, "Yes, I Braddlee, certify that this gentleman's public key is true. This is a true copy of his key." If someone knows me and they trust my judgment about how I would go about doing this, then they can extend that level of trust to that gentleman's public key and use it with a little higher degree of confidence. But that's a very tenuous situation, and it depends on mutual trust rather than any sort of real secure authentication.

And again, with counterfeit keys, it's the idea that it's easy to fake keys and that you really do need to pay attention to who they're communicating with.

Okay. How do I get PGP? Inside the United States, and again for personal use, PGP 2.6.2 is available from MIT. I put up the Web site there because it is, quite frankly, easier to get into

and use. The address for that, for the folks who are listening on tape, is <http://web.mit.edu/network/pgp.html>.

If for some reason you don't have Web access you can also get it from the FTP site at netdist.mit.edu. In order to get it from that site you first have to tell that to that site, log-in as "get PGP," with no password, and it will walk you through a series of questions regarding non-commercial use and export restrictions, which also apply to Web access. At the end of that process, if you answer each of those questions correctly you will be given a secret FTP directory which is changed every half hour. And then you can log-out from the Telnet connection, FTP back in, change to the secret directory and get the files.

Both the Web site and the FTP site will do reverse name service on your domain. So, for example, if you're connecting from a PPP connection you may have trouble with reverse name service on this, and you may actually have to log-in to a shell account and then use a connection that way. The reason it does reverse name service is to ensure that the domain that the software's being moved to is within the United States, because of the export restrictions.

Obviously it is not terribly difficult to defeat this; but that's not really the purpose. The purpose is to try to ensure that the legitimate distribution is happening through legitimate channels.

Inside the United States, if you're going to use PGP for commercial use go to Viacrypt. Viacrypt has licensed PGP, and also has a legitimate license to the [inaudible] since Version 2.4 of PGP. Their Home Page is <http://www.viacrypt.com> — that's a little better URL than the one that's on this resource sheet. So you may want to scratch out the one that's on the Viacrypt contact information and put this one in instead.

The current version of Viacrypt is 2.7.1, I believe. For PCs and Macs, Viacrypt is between \$99 and \$149 for a single-user license, and what you get with that is you get a manual and you get support, which is not to be underestimated. I would strongly encourage you, if you are going to use PGP or a public key encryption product, that you talk to the folks at Viacrypt. They have been involved in the PGP development process for a long time. The company itself seems to be very responsible and responsive. They've had a good presence on the Internet for a long time, and they seem like decent people based on my limited contact with them.

Outside the United States there isn't — one of the interesting things in the history of PGP is within about a day of the time Version 1.0 was released PGP got outside the country. The U.S. Government treats strong encryption products as basically being new munitions; basically cryptography is treated the same way as a tank, a bomb or an aircraft. And the way it's applied isn't always rational, but the laws do get enforced.

One of Phil Zimmerman's big problems right now is that he is currently under investigation for violating these export restrictions, because he handed the program to a friend and the friend distributed it on the Internet. Each of the versions since 1.0 has also become distributed pretty much worldwide, because it is pretty easy to circumvent these distribution restrictions that are being put on [users] by MIT. And I don't want to imply that MIT is being lax somehow in doing this; they're not. They're following very much to the letter of what they need to do. It's that people are circumventing that.

But the International PGP Home Page is <http://www.ifi.uio.no/~staalesc/pgp/home.html>. The "N-O" is for Norway. PGP is kind of suffering from a profusion of versions; the commercial version, the international version, and the U.S. version all have slightly different version numbers. However, the version numbers that are up here and are listed on your resource sheet are the current versions. Even though they don't have the same number they all have similar functionality. The International PGP version uses the original versions of RSA that were used in versions 2.3. There are some advantages as far as that being a little bit faster, and

also it doesn't have some of the restrictions on it as far as the RSA patents don't apply outside of the United States.

M: You may want to point out...

Braddlee: Please do.

M: That some countries do not allow you to bring [inaudible] into their country.

Braddlee: That's right, including France, Iran and Iraq. There's a list, actually; if you go to the International PGP Home Page there's a link off of that Page that goes to a French site that lists the countries other than the United States that have restrictions. One of the things I thought that was interesting was that in May of this year the Russian government outlawed all encryption products that are not licensed by the Russian government.

And it's interesting that as far as the public policy perspective, the United States is actually heading pretty much in the same direction as Russia, Iran, Iraq, and other sort of well-known democracies as far as a model for encryption policy.

Okay. What is PGP available for? It is basically available for most anything you would probably want to use it on. I'm going to assume that most of you folks are going to use it on DOS, Windows, or on a Mac. It was originally written for DOS. The beginning, I think, was the Version 2.3, and there's been a port to Macintosh which has been okayed. It's obviously not a Mac application, but it does work and it works fairly well; the pull-down menus are reasonably complete and it gives decent context-sensitive help.

In Version 3.0, which is upcoming for both the DOS and the Windows versions, PGP is going to be rewritten more for graphical user interface. Right now PGP is essentially a command-line utility; if you love UNIX you'll like PGP. But the two URLs that I've listed up there, for WINPGP, the HTTP is zan.firstnet.net/~cwguidegeib/, that's the location for WINPGP, which is a shareware utility that will work under Windows for encryption, decryption, creating keys and most of the basic things you want to do.

M: [inaudible]

Braddlee: No. But it's listed right on the top of the Page. I think it's 2.1, but I'm kind of guessing. Yes?

M: What is the key length [inaudible]?

Braddlee: The key length?

M: Yes. Is it [inaudible]?

Braddlee: Okay. For PGP the current version will support up to 1,040 — I'm sorry, 2,048-bit keys. Yeah, bit keys.

M: [inaudible]

Braddlee: My understanding is that basically PGP in any of its forms cannot be exported.

M: [inaudible]

Braddlee: In any of its forms. Because it uses RSA, and — because it uses RSA, basically.

M: Then why [inaudible] claim that they [inaudible]?

Braddlee: Because they're using, I believe, a 40-bit key.

M: A 40-bit key?

Braddlee: Yeah.

M: What, what is the limit?

Braddlee: I don't honestly know right off the top of my head, but I'd be happy to find out for you. Yes?

M: [inaudible]

Braddlee: That's right, that's my recollection. I would assume that forty is what Netscape is using and exporting. I'm assuming that they're going to use the maximum that's available to them.

As you probably know, the 40-bit Netscape key has been broken. A gentleman in France did that in the last month or two. It basically took eight computers and giving a supercomputer a couple of days to hack away on it, but it is breakable. That's one of the reasons that PGP is restricted; it's difficult to factor the keys of these large lengths. The larger a key gets — it's not simply a gradual progression; the larger the key, the more difficult it's going to become to systematically break the key. MacPGP has tools for Eudora, which uses AppleScript, and allows it to basically encrypt and decrypt messages from next to the Finder Menu. It's also available for pretty much any flavor of UNIX that you would imagine, and Amiga and Atari, and I'm sure some other folks.

Okay. How do you use it? First you install PGP. For both the DOS and for the Mac versions, this is a pretty straightforward process. It's basically a ZIP or a StuffIt compressed file that you unpack, and it will install itself in the correct directories. I would strongly suggest, although you have it available other places and you can find it other places on the Net, that you go ahead get it from MIT.

You'll want to create a public/private key pair, and I would suggest you use the 1,024-bit key length. It's kind of the balance between something that is highly unlikely that anyone is going to break in the reasonably foreseeable future and having to wait an excessively long time for your files to be encrypted. The larger your key, the longer that takes. 1,024 is kind of the balance at this point.

Get your friends to use the same thing. Public key cryptography only works if groups of people use it, people that you interact with and communicate with, your business partners, whomever. Get other people to do the same thing.

You need to exchange your public keys. There are a number of ways to do this, and one of the easiest is if you have "The Finger." The Finger is a protocol that is available to you, and put it into your plan file. For example, if you Finger my UNIX account, which is braddlee@trapeze.scs.unr.edu, you will find my public key there. Feel free to use it and exchange public key rings. If you have a listing of public keys from your friends there is no

reason why you can't exchange those public keys. That's the idea behind them, that they are distributable.

There are local, regional, and international key servers. One interesting development on that is in addition to the public key server that's listed under the primary WWW resources on the hand-out, there is now a new domain — which I believe is pgp.org or pgp.net — which is going into effect to do international regionalized distribution of the keys. It's going to provide a better, more organized system for distributing your public keys, and also for revoking them.

[Tape change]

Braddlee: If you have a public key out, and it's been compromised, how do you get that information out to people that the key has been compromised, and not to use it anymore?

M: What was that again?

Braddlee: It's www.pgp.org, and I believe it's ".net." If it's not ".net" it's ".org," and I apologize for not knowing that. What I'll do is I'm going to update this list as soon as I get back into town, and I will put that in the pointer on here.

Key fingerprints on business cards. If you plan to use PGP or Viacrypt PGP on a regular basis then put the fingerprint — a small string of digits about 20 characters long and a perfectly reasonable size — put it on a business card. That way when you hand your business card out to someone they can get your public key off of a server, and they can check the fingerprint on that key off the server with a fingerprint on your business card. It makes it a lot easier to identify whether that's a valid public key. Yes, over in the corner?

M: Are those [inaudible] for PGP only, or do they work for any public [inaudible]?

Braddlee: As far as I know they're for PGP only. There is a [inaudible] key server that's run out of Michigan State, if you're using [inaudible]. And I think there are a couple of other distributors across the Net, but these are primarily PGP servers.

M: [inaudible]

Braddlee: That fingerprint is basically a digest of your public key. It's basically similar to a checksum. It's a small digest of what the public key is.

M: So you register with the key server, and then they [inaudible]?

Braddlee: No. You do the fingerprint yourself, within PGP.

M: Okay.

Braddlee: Use the PGP add-ons like Private Idaho, which is Windows e-mail using PGP; the WINPGP tool, and the AppleScript and Eudora tools. They have gone a long way towards making this usable. A year ago the only people that I really felt that I could recommend this to, as far as a real sort of everyday kind of thing, was people who really had a need for it, who were exchanging data that needed to be secure on a regular basis. The PGP add-ons and the new version of PGP, 3.0, I think will go a long way towards making this a tool that everybody

can use. Simply select the right pull-down menu, select "Encrypt," type in their pass-phrase, "Decrypt," type in their pass-phrase, sign, etc.

[You can] basically send secure e-mail. Use it. It doesn't do a whole lot of good sitting on your hard drive; make it a practice to start sending secure e-mail. And use digital signatures. I haven't talked a lot about digital signatures so far, but I'm going to do this a little bit in just a second.

And this is my public key. Any of you who have photographic memories will want to jot this down. That's what my public key looks like. So if you finger my account at trapeze.sc.unr.edu, that's what you're going to see at the bottom of my plan file. And you can see it was done with Version 2.6, and basically it's a field. It has a public key block begin, public key block end, and then the key itself is defined in sign. Right down here, the last line there, the [OMIO], that's a checksum just to make sure that the key itself hasn't gotten mutilated in transit.

M: [inaudible]

Braddlee: That's a 1,024.

M: Does that mean that, that gives you the [inaudible]?

Braddlee: Okay, so what you're saying is that if someone has cracked one key they've cracked every key. No. First of all, it's really, really, really unlikely that the gentleman in France is going to have access to — basically, right now at this point in time, I believe it is accurate to say that for a 1,024-bit key it is just completely impractical to do a brute force attack on a 1,024 bit key in RSA. There just is not the computing power available, even to the NSA or to anybody else.

Now, that doesn't mean that there couldn't be a weakness that we in the general public don't know about, but the NSA might be aware of or that somebody else has found out. But one of the things that I like about PGP, and one of things that makes me feel fairly comfortable with it even though I'm not a cryptographer, is that it is published. The source code is available and the algorithms that are being used are basically the best available tools that are available to the general public. It was not developed out of the NSA.

As far as I can see, based on how I've been looking at this for the last several years there's no way that you can have 100% confidence that any of these tools are going to make you completely safe. And a lot of the safety, a lot of the risks — and we're going to talk about that in a minute — come not so much from the encryption but from how it's used. There are a lot easier ways to get a somebody's information than a brute force attack on a key.

M: But did that person in France, [inaudible]?

Braddlee: No. In other words, if that message that he had was a credit card number, he's gotten that one credit card number after eight days. Okay?

This is a PGP encryption, a PGP signed document. This is a really small PGP signed document, and it has a field that begins the message, the text of the message, and then the PGP signature.

Now, what you can see here is that I have left the message itself in clear text. I haven't encrypted the message, all I've done here is sign it. So what I'm doing here is I have used my secret key and my pass-phrase to sign the document and say that I, Braddlee, am truly the person that created this document at a particular point in time.

This is a tool that you can use also for exchanging information and agreements, and that's one of the most important things that it can be used for — to certify if you're saying something, that it really is you that's saying it. Or if you're entering an agreement with somebody, it certifies that it really is the person that you're entering an agreement with. There is starting to be some acceptance of this as being legally valid signatures. Utah is setting up some procedures for using digital signatures, and there's a lot of other talk, too. There's what's known as the DSS, the "digital signature standard" that is being put forward as a federal proposal, and a couple of other things.

Yes?

M: If you sent me that [inaudible], how would I validate it?

Braddlee: Okay. You would validate that with my public key.

M: Oh, with your public key?

Braddlee: Right.

M: [inaudible]

Braddlee: Exactly. I would — how would I validate this? You would validate it as a recipient, you would validate it with my public key.

M: The whole message could have been encrypted, though?

Braddlee: And that's what it would be like if we encrypted the whole thing.

M: Should I separate the two, and [inaudible]?

Braddlee: No. Let me back up there for a second... The question is, can you forge this? Can you forge this signed document? No. Because what happens is PGP looks at the document itself, and the contents of the document are used as the basis for the signature. If you try to graft another message onto a different signature it won't process; it will come back as an invalid signature.

M: [Inaudible] secret and public [inaudible]?

Braddlee: Yes, it's 1,024 bit. Yes?

M: What is [inaudible] size of a file [inaudible]?

Braddlee: Oh, good question. What does PGP do to the size of the document? Actually, what happens is that PGP, when it compresses and when it encrypts the document, the first thing it does is it compresses it using the ZIP compression algorithm. Same tools, basically, as, as PKZIP. So it compresses it before it encrypts it. However, what I've done in these is taken that binary compressed information and "ASCII-fied" it, turned it into standard text, A-through-Z, I-through-10, standard punctuation characters. The process of doing that changes the bit-length of each of the characters, so it expands out by about a third. But anyway, what you end up with when you take a text document and you encrypt it using PGP — even if you turn it back into

ASCII so that you can send it through e-mail, because most e-mail systems don't deal with non-text characters — you're still going to have smaller document.

M: I thought I'd just make a point.

Braddlee: Please.

M: [inaudible]

Braddlee: That's true.

M: [Inaudible] allow it to be a constant thing [inaudible].

Braddlee: Exactly. What the gentleman was saying was that one of the things that PGP does, and it is a good idea, is that using the ZIP compression to compress the file before it's encrypted isn't just a case of efficiency in sending the file. What it does is it removes the redundancies that people can use to try to guess the contents of information, so basically it scrambles the file to a certain extent. It removes redundancies by compressing it, and then the encryption makes it even more secure.

M: [inaudible]

Braddlee: Well, remember that PGP isn't e-mail software itself. So usually what you're going to do is you're going to encrypt a file and then you're going to send it as an attachment.

Okay, so that we don't run out of time, I'm going to try to move on.

[What are] some of the risks of using PGP? It is a poor idea to use PGP on publicly accessible computers. That means, for example, that we would not install PGP on our primary UNIX host at the university, even though we would like to, because you don't want to transmit unencrypted pass-phrases over a network. You really don't want to leave people's secret keys out, even though the secret key isn't much good without a pass-phrase. It's just not a good idea. In fact, it's not a great idea to even use PGP on a computer that's attached to a network. It really depends; a lot of these things are things that you're going to have to look at in the context of your own environment. How secure does my information need to be? Try to take your risks from an informed perspective. You're probably not going to be able to eliminate every risk in the universe.

The question is, can you understand what those risks are and take them from an informed perspective? I would not use PGP on a multi-user UNIX system. I would not use PGP if I had to log onto a computer over a network.

[I want to mention] compromised keys and pass-phrases. If someone knows your pass-phrase to your secret key then they can sign documents as you, and then they can decrypt your messages. Basically, they have access to the whole tamale.

Forged keys — we talked a little bit about that earlier.

People being able to spoof who they are to you. There are things like "Man in the Middle," and there are a number of ways to do this.

Traffic analysis. You don't necessarily have to know a whole lot about what people are saying to each other; just the mere fact that they are talking to one another can be useful information. If I'm sending a lot of mail to Bill Gates at Microsoft, that's probably going to tell you more than if I'm sending mail to Mary Jane at portland.edu or something.

Un erased files. If you're smart you will use PGP, you will use a RAM disk, you will not write on your hard disk and you will have to watch out for Windows swap files. You have to watch out for files left behind on a disk. If your original is left behind on a disk and is on a computer that is not secure, which is easier, doing a massive cryptographic attack against a message or getting into somebody's office and using Norton on their hard drive?

Viruses. It's theoretically possible that a Trojan Horse or a virus could be created that would capture your pass-phrase as you typed it in.

"Tempest attacks." this is a little obscure, but it depends on how you like to live your life. It is possible to monitor the electromagnetic fields coming off of computers; you can sit in a van across the street from someone's house and monitor what the keystrokes are. You can shield against that. This is a question of: is it a risk? Do you think it's really a risk that you're subject to?

Bogus time stamps on signatures. Just because something is signed at a particular time doesn't necessarily mean that it was really signed at that time. I mean, I can go in and change the time on the CPU, and it has a bogus time stamp. One way to avoid that is to use a trusted third party to certify that the times and agreements exchanged with digital signatures are accurate.

And again, notice that I put this at the bottom, "Crypt Analysis," which is brute force and other attacks against the PGP key, against the RSA keys.

How do you get help with PGP? Read the manual. Phil Zimmerman has done a very good job of writing the documentation for PGP. It is also available as a book from MIT Press, *PGP Users Guide*. It is about \$14, if I remember correctly. There is now some other good documentation and books coming out; on the last two pages of the handout I list those. If you need help and you're a commercial user, or if you're a non-commercial user and you're still struggling, get a supported version that will give you somebody that you can call. That may be worth the \$100 or \$150 for you.

The UseNet newsgroup alt.security.pgp is a good place to look for information. They are not the first place that I would post a message that says something like, "How do I create a public key pair?" I would use that more for reading, or for more advanced questions. Read the FAQ files that go with both of those newsgroups.

There's a list of other newsgroups and mailing lists. The list of pointers to EPIC, the Electronic Privacy Information Center, on the third page of the hand-out has a good list of those things. If you really, truly think you found a bug, and it's not just that you're having trouble with something, send e-mail to pgpbugs@mit.edu.

And lastly, don't bug Phil; really use all of these other things first. And then, only then, if you really think you know what you're doing and you haven't been able to find a solution to the problem, then you may want to try to get in touch with Phil Zimmerman directly.

Okay. Is PGP legal? We've talked a little bit about this. If you're a commercial user you need to get Viacrypt's version. The RSA libraries are not licensed on the MIT version for commercial use. Versions 2.3a and below are in violation of the RSA patent rights; Versions 2.6 and above are not. So as long as you're using 2.6 and above, and you're using it for non-commercial use, go ahead and use the MIT distribution.

Do not take PGP on your hard drive out of the U.S. or Canada — it is a felony. You are exporting munitions. And frankly, I would not want to be the test case on this.

However, it is okay to send encrypted e-mail internationally and it is okay to use digital signatures on stuff that is going overseas. It is okay to send encrypted messages overseas. The U.S. versions and the international version of PGP do interact, they are interoperable, so you don't have any interoperability problems between U.S. users of PGP and international users of PGP.

There are also some alternatives to PGP that you may want to look at if you've decided for some reason that this is not appropriate for you. There's the Privacy-Enhanced Mail Standard, which is not software but an Internet standard, an IATF standard. Software that is written to that standard uses different key management. There may be indications where it's appropriate for you. A couple of years ago I looked at [inaudible] because we were concerned about RSA and the licensing for RSA. At this point the number of people using PGP completely overwhelms the number of people using [inaudible]. For digital signatures you may want to take a look at the digital signature standard which is coming out.

Is PGP secure? That's kind of a difficult question. [Bruce Schneier] in *Applied Cryptography*, which is a very well-respected text on encryption and encryption systems, says that PGP is well-designed and nicely coded in the public domain, the closest you're likely to get to military-grade encryption. But what I'm going to add to that is that your privacy is secure only if you're using PGP properly, and if you can reduce the other risks. In other words you can use PGP, but if other people know your pass-phrase or can read your hard drive it doesn't matter how secure it is, because you've compromised your own privacy.

Phil Zimmerman is currently under investigation for a felony by the U.S. government for the export of the original version of PGP. He has accumulated thousands of dollars in legal fees and is basically fairly heavily into debt, even though most of his attorneys are working pro bono. He does have a legal defense fund, and there is a listing of contact information on how to get in touch with his attorney in charge of the legal defense fund. If you want to make a check out to them, it's the Zimmerman Legal Defense Fund, and you send it to [Phillippe Debois], Esquire, 2305 Broadway, Boulder, Colorado, 80304.

And there's also the Web site down there, <http://www.netresponse.com.zldf>. Something that I would like to do is — I'm not really being paid for this presentation. This is something I volunteered to do, but I'm going to be contributing a portion of my speaker's fee for a presentation I'm doing Wednesday to the legal defense fund. If anybody would care to contribute feel free to come up afterwards and toss in your nickel or dime or your lunch per diem right in there, and I will be happy to send it forward as a certified check.

Okay; [what's the] future of PGP? There are a couple of neat things going on: PGP Phone, which is secured telephony. MIT — actually, I'll tell you what. Can I hand that to you, and you pass that around? Thank you. PGP Phone is secured telephony. There is now a new version that has just been released in data from Web MIT to you network PGP Phone, and it will work over a modem at this point. There is an Internet option coming up, and this is a very neat tool. I would suggest that if you're interested in this then go, get a copy and take a look at it. It works right now, basically, on Mac, on Macintoshes only; but there is going to be a Windows version coming out in the next couple of months. It's a very interesting tool to have secure private telephone conversations. It has an interesting system of key exchange, and authentication based on voice recognition and encryption.

PGP 3.0 is coming up, and it's going to have much better GUI support. It's going to work much better on Windows and on Macs. It will have, rather than one secret key, two secret keys — one for signatures and one for files. There are reasons for this. For example, if you are required to give up your secret key for encryption files as a result of a subpoena your key for signatures would not be compromised. That's one reason for having two keys.

There is a possibility it will have support for encryption standards other than RSA and IDEA as options. And it's also a possibility that it will have some options for interpersonal key escrow, where you can give two friends half of your public key so that you can retrieve it later if you need to.

Okay, thank you very much. We're a little bit over time, but I'll be happy to stay down here and answer questions for you. I appreciate your attention. Thank you and have a good afternoon.

PUBLIC RELATIONS THE INTERNET AS A PUBLIC RELATIONS TOOL

MODERATOR

Tanya Mazarowski
Public Relations Director, Mecklermedia

SPEAKERS

Jamie O'Donnell
JONA Group
Nola Armijo
Partner, JONA Group
Pam Alexander
President/Owner, Alexander Communications

Tanya Mazarowski: Welcome everyone. This is the Public Relations in the Internet Seminar and we're going to go ahead and get started. We're going to have some technical people working up here, but I don't think they'll be too distracting.

When we were designing this PR track session, we had several things in mind. We knew we didn't want a bunch of editors up here telling you, "Well, I don't want to get faxes, but e-mail is okay." And "I'll never read my mail," and "I'll throw out everything fax that comes through the machine, but if you send me a FedEx I might open it." So when Nancy Nelson and Pat Lane at Meckler came to me and said, "Well, what, how do we use the Internet for PR? How can somebody use this new medium?" We had to think about who we knew in the PR field who really understand the value of the new medium and could take their time to share their expertise with all of you today.

Each of the speakers we have here today have taught valuable lessons in PR, and were specifically hi-tech PR in dealing with the Internet, the Net community and the network itself. The Internet community compiles not only print journalists, but your direct consumer.

Unfortunately, our first panelist, Brian Johnson, was unable to be here due to the last moment personal emergency, but we're fortunate enough to have JONA Group here, as well as Pam Alexander, President of Alexander Communications, to share some of their insights with you. We first have the JONA Group. They're going to be talking quite a bit about their extensive experience in the Internet field.

Last spring I spent a few weeks on the west coast in a General Meckler Press Tour. As our offices are located in Westport, Connecticut, of course, the hi-tech Mecca of the east coast, and we realized after the tour, how essential it was for us to be able to tap into the Bay Area resources, and have someone on the west coast with an ear out for our publicity interests.

The newly formed JONA Group, comprised of seasoned professionals with hi-tech backgrounds was perfect to suit our needs. JONA organized and executed the recruitment of media and analysts for this year's Fall Internet '95 Show. We've only, we've heard only good things about the quality the press registered for this event from our exhibitors, but, and the press, well, let's just say a well-known hi-tech journalist from the Wall Street Journal received a hundred and fifty phone calls on Friday, but still showed up here in Boston ready to cover our show. Yeah, the JONA Group is working with us, and they're doing very well, not only for Mecklermedia, for a variety of Internet clients, including BBN (Planet), E-Ticket, GO Net, Open Text and Harlequin.

Please welcome Jamie O'Donnell and Nola Armijo.

Jamie O'Donnell: Thanks Tanya. Is the, is the volume in this microphone good? No problems?

M: Louder.

Jamie O'Donnell: Louder? Okay. Can you bring that up a little bit volume-wise? Is that good?

M: [inaudible]

Jamie O'Donnell: Okay. How's that?

M: Louder.

Jamie O'Donnell: Okay. We're going to do this and see how this holds.

M: That's better.

Jamie O'Donnell: Better? Okay. We'll try to keep one hand real stationary. When Tanya asked us as we were getting ready for this show this, this October, and I'm really, really amazed having been in the PC industry for about fifteen years, and to have, to sort of see the whole PC revolution happen in the early 80's, and then the watching the Macintosh shows in the mid-80's sort of, you know, take flight and grow with great, great excitement, to see it for a third time in sort of my career in technology, a lot of excitement and a lot of enthusiasm.

When Jarrett Saburg was asking me yesterday what, what I thought was the most interesting thing about the show, I think the most interesting thing is you can contrast all the money that's been spent on the Windows 95 launch in 1995, both advertising and public relations, and all different types of marketing vehicles, right down to the Rolling Stone, and take a look at what's happening on the floor down here, at the grass roots developer level and vendor level, and the excitement and the juice happening down on the floor, I think is, you know, that, that, that, third time around that I've seen in the industry that there's, there's a platform coming about with a great amount of excitement. And it's really tremendous to see down there. It's also a model that is very much emerging and only taking shape now, and it calls for some very, very, very high degree of adaptability to, to do promotions and marketing on the Internet.

And we had a choice to talk about two things. To talk about, you know, the formats of press materials on the Internet, who to contact and how that list is growing. And I made a decision to go another direction. And we can come back to some of those questions, is there are those type of questions there, sort of, you know, leading off. But I want to talk more about the phenomenon of the Internet, how it changes the model for public relations, and the process that we're working on day-to-day, and really test piloting. Because it's very, very much in an early adopter phase, where you've got to try things, test them out, see how they work, measure it and go back and test again.

So Jarrett, do you want to start on the slides over there? Okay. You can go right on to the next one.

Public Relations on the Internet. Well, it's certainly not a, a mature or static model yet. What you learn today about promoting content or services, changes almost every day. The, as we were getting the press registrations for Internet World and getting them into the database, there were new vehicles coming in every day that weren't at Internet World six months ago in San Jose.

You need to keep your peripheral vision open. There are new things cropping up on the left and the right every day. Things you need to go in and research. Sometimes they're not easy to research. Some of the hardest ones have been [getting] a lot of interest by Internet enthusiasts and some of the easiest that have been getting a lot of coverage, as well as some of the young Web enthusiasts, and I don't have to spend a lot of time on [them]. And it takes a lot of research to track down who's working on those, the editorial page and how to reach those people, and how to work with them is not clear yet at all. But there's a lot of interest with two or three of them from our experience.

You have to expect that some vehicles are going to become critical overnight. Others are going to become critical over time, and some of them are never going to hit the target. You know, we, we've seen new magazines from Meckler, we've seen new magazines from Newsweek, like Virtual City, we've new magazines from Ziff, *Internet Life*, that's being launched at the show here today. Some of those are obviously going to take hold and hit the target right on. Some of them are not going to, and the best you can do is test with those and pilot project with those.

If we take a look at two or three examples, I can, that I can think of in terms of examples of things that took out, took off with a lot of serendipity and a lot of test project along the way. You think of NetScape's distribution mechanism of providing the browser free from a download and you know, Meta Company, that's a market leader now in that segment, and wasn't shipping product last December. Open Text is a company that has a indexing engineer down on the floor here and we helped Parker Nichols on the west coast support that client, and Open Text got a lot of publicity once it had a deal with Yahoo, anything happening with Yahoo and Netscape, just draws publicity for other companies. And third, you take a look at the incredible amount of take-off coverage that's happening for things like Real Audio and m-Take Video and VRML in the last few months, that, you know, there was literally no coverage if you go into a database search six months ago.

Next slide, Jed.

And all this means, is that you have to sort of learn what state-of-the-art, experiment, test the limits. I think a couple good examples recently of testing elements and experimenting, you think of IBM's takeover of Lotus back this summer, and that Gerstner took his takeover letter to Manzi, put it up on the, on their Web page and on the Internet, made you know, their position clear for the world to see without violating any SEC rules, but sort of you know, change the model a bit about how you make public information available using the Net.

I don't do this every trip, but every couple of a trips I help myself to United Airline's magazine from the plane, where there's an article that I, that I have to read or I want to share it with somebody when I get off the plane, and I thought there was a very interesting about merchandising Web sites in the October issue, when they talked about the hot, hot, hot page. It's one I've seen a couple of times.

I don't spend a lot of time, but it's one that frequently pops up as I watch some of the younger people in our office surf, and they talk about testing and experimenting with the size of the icons, how graphically it's written, both for domestic audiences, as well as international audiences, how they measure user response to the page, in terms of buying patterns, as well as how they respond to it. A lot of good information about how a company takes a page, comes up with a concept, what's going to work for the user, tests it, and modifies the page regularly, as a result of the user feedback it gets.

Next page, Jed.

The Internet's many things. It's both a medium and it's also a distribution channel. We've had a couple of clients where, they've actually been using things like the Internet Shopping Network, Cybersource, a number of the on-line distribution mechanisms to sell products, and

some interesting things. When you think about Netscape, Netscape really developed as a company overnight by using the Internet as a distribution vehicle.

When you think back to a couple of years ago about in software and Doom and creating a cult game there, that was all done really with Internet pass-along, and e-mail pass-along of the product.

We're currently working with a Windows 95 help product that had to make a very, very hard decision about, they tried to go in two flanks and go on-line to distribute the product and try to do a retail product in the same time that Windows 95 was coming out, or do they only do one or the other. They chose the two dollar bet of trying on-line and what their research is showing them, it's a company called E Ticket that has a Quick Tutors '95 that they have licensed. It's available through AOL in the Windows 95 form. It's available in Prodigy in the same form. It's available in the Internet Shopping Network. And what they've found is that, and one of the founders of that company is a retail channel expert, so he's been tracking what's happening on the channel with the products, and there was a good six to ten products in the channel of a similar ilk, that are now going into the return phase, getting returned to the vendors, at a much lower price point. This particular client is getting downloads of about three thousand units a week through three different on-line forms. So very low cost and you know, building a market presence in that particular category.

This is not meant to wow a lot of people, but this just a subjective experience. And I'm not talking about some of the more consumer-oriented PC trades, and I'm not talking about some of the trades that are, Meckler trades and others that are, that are dedicated to on-line. I think one of the real challenges of doing on-line, public relations for on-line products, that there are traditional PC press that are not quick to embrace a changing model. As we have been promoting some products that are only delivered on-line, we're finding that there's often sort of puzzlement about new content categories. You know, where does this fit? You know, what are we going to do with it? It's, how are we going to review it? Because the models are very set about where products fit and how they get reviewed. There's often resistance to reviewing on-line products only. We've had some of the top-tier business-to-business computer trade saying, "If it's only going to be an on-line distribution, we're not ready to review the products that are coming up in that way." And you can, you can put together a press release, the documents, you know, AOL says we've got five thousand units coming down from our site in a week. We've got, you know, Prodigy says we've got, you know, four to five thousand, and in particular, press release saying, "How many units are selling?" And it's very, it's still a real challenge to, to sell downloads as a, as a barometer of product success.

What are some of the unique characteristics of this animal called the Internet right now and how has it changed public relations? It's a medium very much defined by speed. When I think about learning to do public relations with newspapers, you know, that model has been set for a long time. The same with magazines. TV is a, is a real long lead medium to work with in terms of placement. So you might work six, seven months on a placement, even in some of the computer-oriented programs. Same with radio. However, with the Internet, there's opportunities to try different things every day, revise your course weekly, get feedback fairly frequently.

With two of the clients we have in on-line products only market, every two weeks we take a look at what's happening with them in terms of their pages. What kind of response they're getting? Where is it coming from? And we adjust where we're going to go next based on that.

It's a technology defined phenomenon. We think of things going from cool new technology to early adopt your products to mass market products, and it's still very much in

that sort of technology category space. And as a result it's very volatile, and it changes a lot. And the user base right now is defined by high growth and dramatic change.

O'Reilly and Associates, who are one of the exhibitors on the floor, and I believe we have one of the research analysts sitting up here who worked on that, if you want to ask questions of her later, just completed a study of thirty thousand homes by looking at their press release in their kit. And you know, we're beginning to get a better focus on, on some of the sub-groups that we've not known much about. I mean, their study now shows that about 33% of the core Internet users are female, and that 36% of the commercial on-line services users are women. So there's data beginning to develop. They're saying, "How do you target women? What are they doing on the Net? How are they spending time? What are they interested in? And what are their information sources for the Internet?"

It's a product. No, it's a medium. Actually, it's both. It enables vendors to reach customers directly, and enables instant mass communications in some circumstances we've all seen. And as a result it creates new PR opportunities and it also creates real pitfalls.

If we take a look at the Intel Pentium chip example, and problems they had earlier in the year, they greatly underestimated the Internet and in e-mail as a vehicle to spread word about how the consumers really felt about the problem. And they weren't prepared for this as a new mass communications vehicle.

It also can create overnight hits for sites. I think of one, an alternative music site that several people in my office go to once or twice a week. And it was out of Santa Cruz, not there a year ago, and it's had phenomenal success, because it has appeal and the medium is right.

When you think about where we've been in the last ten years, and you think about communications models, if you go back to you know, Regis McKenna in the early 80's, he would talk about, you know, vendors would have a product, they'd encode a message, they'd go to the media to try the message out to see how it was received, the media would be conveyors to the end-user, and there would be feedback both from you know, PC Magazine and the media outlets, as well as from the users. And from there, vendors would, you know, hopefully tune their product plans based on feedback coming from two different directions.

With the Internet, I'm finding that it's greatly changing in terms of what a vendor has to consider in terms of the communications model.

What, what we see happening now, is if we have a vendor coming along and saying, "You know, who we going to go see on a press tour?" It's really a, a, a bi-directional situation from step one. What they really need to do, is they need to go out and they need to find customers to put their service or their content offering in front of, and get feedback from the customer right away and create a word-of-mouth campaign on whether they've got some hot contents or not, and then they need to go to media in this market as creating additional noise. But the role of the media here is, is, is in the process, is a really, really shifting from our experience of it. And if I told someone, you know, what their, what their main challenge was going to be in launching a product through the Internet over the first six months, I would say it would both be creating visibility for your company and your product concept, because there are new product and company concepts emerging as people go on-line completely, and convincing the market analysts and the press that you have a really interesting new model that's worth following. But at the same time you need to go to the customers directly with your content. And it's a, it really means sort of working two fronts at one time, compared to a more linear approach.

We, to give you an example about how the influencers are already changing, I think many of you probably remember the marketing Computers issue from the springtime, it was probably about the April issue where they did a, a rating of the computer trade press. Who's hot? Who's new and ascending? Who are the old guard that still have a lot of influence? And

when you look at that list, it was really looking at people who were reviewing PC products, whether they are business-to-business or whether they were consumer. But they were packaged products for the most part.

There was very, very, very little attention paid if any, to what's happening in terms of who the influencers are in the on-line market. And it, it, it, it's not always an easy one to peg.

And one of the things that we do in, in our office for our clients is, we have several people in the office who are on the Net every day. We're in San Francisco. They're friends with people who work at Hot Wired. They're friends with people who work at C-NET. They're friends with people who work with, who develop Web directories. And what we'll do on a Friday afternoon is we'll take a new content product that hasn't been launched yet, we'll invite everybody over for a glass of wine or martinis, and we'll say, okay, "Here's his content. What do you think about the tone of it? What do you think it needs to be successful, and where do you think it needs to get covered?"

And we recently did that about two weeks ago for a product that's going to be sort of in the murder mystery content category. And we sat down, a friend who works for Wired, Hot Wired, and a few of these vehicles, and we did a little, you know, "What ten places do you feel it has to go first?" As a way of coming up a map of where, where do we feel it needs to go. So we talk to the target audience, a small informal focus group.

And here's a list from 25 to 30 year-olds who are Web enthusiasts, about where they thought this product needed to be covered in order to get, to get attention from the target audience. They said, "Pathfinder." They said, "Hot Wired." They said, "Web Review." They said, "C Net On-line." The only paid one they mentioned was Mercury Center. They said, "Yahoo, What's New?" They said, "Computer Life." They said, "2 E Scenes, Urban Desires and Word." They said, "Buzz Net." And they said, "Gina Smith in all mediums." Now Gina is very well-known in the Bay Area between you know, her column in the Sunday Examiner, as well as her radio program. I'd be interested to see if we did that in other parts of the country. But Gina has quite a lot of say out in that marketplace. But you know, this, this list doesn't map at all to products pre-on-line content products. It wouldn't be the top ten list for even a consumer software product.

Now what does all this mean in terms of strategies for on-line PR? Well, the role of the influencer has mutated from product reviews to a media critic in our mind. And if you check out Cutting Edge, E-Scenes, you're really looking at sort of entertainment type reviews. If you examine the content of the Internet Life I was looking on the floor at yesterday, you're really getting into content entertainment-type reviews or information-type reviews.

So what does this mean for PR professionals? Well, the map, the process that we're following right now that we feel works best, given where the market is, and we may modify this, at a step, track step, but the model that we feel works well right now is first we take something that we're going to launch and we conduct these informal focus groups with Web enthusiasts, to get a sense of what's there, what's their reaction to it, what's the one in order to make the on-lined property as interesting as where it may live on TV or in print or somewhere else.

Then from there, we'll prioritize and segment the media, and we'll test everywhere cheap. We might start with the top ten list we had, then we might go to some of the top ten daily newspapers that all have what's new on the Net sections, then we might go to the syndicated PC radio programs. If you look at their media kits, all claim to have a high number of Internet enthusiasts listening to them, go to some of the computer syndicated TV programs. We segment the media and say, "Okay. How many of these make logically sense, and what's the order we want to approach these?"

Then we try to work with the vendor to map the press coverage to hits on the Web page. We do both on-line searches as well as hard copy clips in the office to say, "Okay. If we

got the *USA Today*, what's new, hard copy coverage on Friday, what did that do for the page over the next five days?" If we get covered in *Computer Life* in the issue at the stand on the, you know, 16th of the month, what did that do for hits to the page. So we really try to help the vendor understand, aside from our best guessing and our best sort of informal focus grouping, what hits are working for them.

We have a number of vendors that are talking to us about, as they're setting up their pages, they're getting ready to put vehicles in place to say we're going to ask the user when they come on, what led you here in the first place so we can begin to map the information sources issue better.

There's also the opportunity now, if you go down to the floor and you pick up the kits and the information from the people that are down on the floor, there's three or four that are, whether it's Data Quest or Writing Associates, there are three or four research oriented firms that are coming out with substantial studies now about you know, who is the user, what are they doing, how are they changing, where do they spend their time and what are their information sources. And the more of that you can do of that, I think the more you can feel confident about the model.

And last of all, I, I mentioned, I think it's you know, it's not a static picture at all. We know that's it's changing from month-to-month. I'm sure we're going to feel that you know, it's even changed greatly as we, if we convene in San Jose in March, and that as a result of that, you need to constantly be monitoring and reassessing who the customer is and the critical influencers, in order to reach those customers constantly. And you need to monitor what is happening and what is new on the Net constantly. And you need to take your public relations and view it as, as, as fluid as your Web page, and that the model needs to be evolved and changed and altered, as frequently as you probably have to alter your Web page to keep it interesting and keep it up-to-date.

I think Nola wants to just spend a minute putting a couple of slides up to give an example of what kind of interest is happening with some very consumer-oriented comment.

And Nola, did you want to do that from up there?

Nola Armijo: No, I have my [inaudible].

Jamie O'Donnell: Okay.

Nola Armijo: You're okay. Well, Jamie mentioned one of our clients is E Ticket. And E Ticket's a...That's page two Jed. E Ticket's a combination of a Web page and CD-ROM company. And they came to us just like two weeks before the Miss America Pageant and said, "We're going to put up a Web page for Miss America. We have the rights to you know, all the information from the past seventy-five years. We can put up photographs, contestants this year," which they did in fact do. And eventually, they're going to use it as an outreach effort really to give young women information who want to participate in pageants. Well, how, what they need to do in their local states in order to get connected and learn more about how to participate in beauty pageant.

Well, this was, of course, as you might imagine quite, quite a challenge because, you know, it was great because we had Miss America coming up in a week, but where were we going to, how were we going to try to trigger some interest in a Web page? So naturally, we did the obvious things. We did a press release and we sent it out to 150 print sites and broadcast Web sites. And we also got the Miss America Organization to distribute the information at the event, and then we, we, we've put together a very highly-targeted list of about twenty or thirty national publications, national daily papers that list Web sites on some

basis, once or twice a week, and we were able to get placements in very high profile papers, because this was kind of an interesting novelty. We also got something in Reuter's and of course, Gina Smith and On-line Today.

Now what do you do after that? I mean, they're only going to carry your information once. So, and to me, this is the most interesting, one of the most interesting things about the on-line world, because it's, it's really, it's as much a consumer medium as anything else. I mean, people gather at places of interest to them. And so the next thing you have to do really, is to find places on the Web that might be interested in Miss America, where there's a common interest about beauty and fashion, and then the next thing would be to go to print publications that list Web pages. And we're working on some of these longer lead publications now. If E Ticket's expecting to come out with a CD-ROM with all the Miss America information, at the end of this year.

Are there any questions?

M: The two points you want to make out of this case study was one that as you re-prioritize media, you have on-line vehicles. Really the publicizing in on-line, and the on-line opportunities are jumping to the top of the list, because they're more immediate and they're more quick. And then going to the more traditional print vehicles, come second or third, and the broadcast vehicles come, you know, coming into second. So it's kind of flipped over from, from what it was in the PC products medium.

The other interesting thing we're learning in promoting on-line pages or on-line properties, Web pages, is that the reporters out there, A, want to get onto the page before it's actually launched, and they want someone to be able to take them through their page in about five to ten minutes flat. If you're the Reuter's reporter or the USA Today reporter, you want, you know, you want to be able to go in and look yourself, then you want somebody to talk through what they want to tell you about it in about five minutes flat. And for most clients, that means getting used to having a demo script for an on-line page. That's sort of a new animal for them saying, "In five minutes we've got to get through. What are the highlights we want to show them and our philosophy about the page." This was a good example of that.

Nola Armijo: There's a man over there. Over here. There's a man over there.

Jamie O'Donnell: Do you want to take a question now or do you want to continue?

Tanya Mazarowski: We're going to continue with one more, our last panelist and then we'll open it up to questions. Oh. We've got with us, we're lucky to have with us Pam Alexander. She's the president of Alexander Communications with offices in San Francisco and Atlanta. And she's here to talk about some of the hot public relation sites on the Internet. Are we surfing? We're surfing?

Pam Alexander: Well, no. That part of it isn't going to work so what I can do though is show you guys some sites you might want to look at from there. Yeah, I think it's...First before I start in this...

What about now? Is this better? I'd just like to get a sense of who you all are. And if you could maybe raise your hands if your primary job is PR either in your company or with an agency. So it's maybe a third of you. And for those of you, whether you do PR primarily or not, how many of you have Web sites where you are trying to reach the media, whether it's market analysts or journalists? Okay. So maybe when we get to the Q & A part of this, you could talk to us about some of your success stories, what's working well for you. And I can seem to go

over there, but I'll just run through these slides really quickly. We were hoping to be able to get up on using actually CompuServe's brand mosaic to launch us into the Internet and look at some sites that I think are of interest. And some of these companies might actually be in the audience.

But Ventana is one. They've got, and some of you may have seen it, they have a press club. Novell has got a multi-lingual international Web sites for journalists, so that people around the world can access what they're doing and they're press releases and every language that they ship product in. So I'll try to give you a list at the end and you might want to check it out, because you could appropriate some of those things that might make sense for your company. I know all the lists, whether it's *Yahoo* or *Lycos* or whatever, have some good sites listed. And actually, I just heard from somebody today that Ketchum has a really good site, Ketchum Public Relations. I haven't seen that, but I understand it's really good.

So just whipping through this pretty quickly. A little background on us before we get into these facts and figures, we've been doing hi-tech PR for over eight years, and we're based in Atlanta and San Francisco, and we have an office in London that's very small. But the Internet and on-line has made that possible. And working with people like CompuServe, we've been able to link all of our staff that way, and communicate with journalists and have, as long as we've been in business via e-mail.

That might be one of the questions to ask all of you, if, raise your hand if you are currently communicating or have for some time with journalists via e-mail? So, okay, I think a lot of us, you know, in addition to all the points that Jamie and Nola made, we might see the Internet as really an extension of what we've all been doing who've been on e-mail, communicating with a target audience of journalists and market analysts, and now that interactivity is probably more enhanced.

But this is just a little bit of background that, I know this a week full of research about the impact in the Internet, and this next slide Tanya might be able to update, is the latest number of subscribers, 208,000?

Tanya Mazarowski: 265.

Pam Alexander: See, it's probably growing by the minute. So, I think we're all used to this. And this is the environment that we're making our decisions about in terms of applying the medium to what we do in PR. The example that Jamie used about Intel, I think we all remember from almost a year ago when they were caught by surprise. And the, the principle that we've all learned, which is if you don't tell your story yourself, other people will tell it for you. The Internet, I think we've all seen, facilitates that more than anything else. But the speed with which the communication gets out and the fact that the data is there and easily appropriated so that people can, can run with that. And I guess, when I say "people", I'm talking about journalists. One good quote that I saw from John Markoff at the New York Times recently was "I used to feel like the used Nets and some mailing lists were my own private backyard. In the mid-80's, I would get a story a week from Comp.Risks, but now there's, if there's something good, dozens of people see it."

So I think maybe we're feeling like we're all trying to compete in this new medium to, you know, either draw attention to a Web site and what you have to say. But I think journalists are also finding that they're, or at least those that were kind of ahead of the curve where they would be able to go to sources and get information that, that now they have to sort of dig deeper. And so I think we'll all be working on this together to find the best ways to both disseminate information and find the best sources for information. And I think that kind of sums up that page. I've only got six or seven more slides.

But what I was going to do is going into the Web sites of these three companies. I mentioned Novell. They've got a multi-lingual site. And HP, gee, that slide is sort of in process. Theirs has got all their press information updated constantly. I think a lot of you had said, seen, what digital has been able to do, not just with PR, but in selling product via the Net. And we'll just change that. This is new program for me. Anyway the Novell Global Reach. I think the emerging technologies that we're going to see on the Internet, real-time video and audio and this show is one where we can walk out on the floor and see that happening, and the collaborative environments. So there they are.

I've just pulled some of them down. CompuServe's home page. I know Russ Robinson will be up here in a minute to talk about what he's doing from within the corporation. If you haven't checked out, OOPS, well, I'll be able to get through this. Meckler's home page, you know, the I-World that's specifically pulled together for this show. You know, Yahoo and the other directories. If your company isn't listed on every directed you should be listed on, that's one important first step to take. Again, Ventana, the let's see, well, let's cross our fingers.

Tanya Mazarowski: Stop. Stop.

Pam Alexander: Oh, well, it will be okay. The, okay, well, all right. OOPS. Sorry. Okay. The, okay, well, I'll just get out of this and we'll just go off-line, because I don't have my battery with me. I'm sorry you guys. Okay. Tanya, can I [inaudible].

Tanya Mazarowski: Does anyone have any questions for our panelists? I think we had someone right over here.

M: When the speaker talked about the [inaudible] print media on the Internet, I wondered if you would have any metrics on how print media, [inaudible] needs to get to [inaudible]?

Pam Alexander: No, I don't. I mean, the real answer is I don't have any real information. But I do think that when you have something that is as highly focused and targeted as something like Miss America, and it's kind of unusual subject to find on the Internet, you have to go to print vehicles in order to drum up interest among people who would be interested in that kind of on-line information.

Tanya Mazarowski: I know we do have some information at Internet World. It's very easy for us to classify our readers, because we know all of our readers are most likely on the Internet. With a magazine like *Mirabella* or *Elle* or *Vogue*, it's a little trickier for them to do their reader surveys.

Jamie O'Donnell: We've been doing some placing in SPA sponsored [Cyber's Affair] contests over the last two weeks...

M: Would you mind using the microphone?

Jamie O'Donnell: Sure. Just another answer to that question. We've been doing some placement work for the SPA sponsored Cyber Safari contests over the last couple of weeks. And we had a long enough lead-time on that, that we managed to do placements in most of the major daily newspapers on-line versions, as well as print versions. And they are going to be tracking the, the, the coverage or the traffic that happens to the site, based on coverage from both mediums. So there's going to be some information coming out of there from SPA as to if

you take a look at all the on-line sites where it's promoted, as well as print, how did that stack up in terms of interest in the program. So experiments like that are in the works, and I think that you know, there's a number of them happening where there will be some information happening where there'll be some information coming out of that.

Tanya Mazarowski: Just two more questions, because I know we're running over into our break.

M: We've had experience which we, with the PR on the Internet [inaudible] on-line. And then when we approach the print media, they refuse to accept any, the articles that already appear on the Internet. We were told that if we wanted to, [inaudible] print media before, and accepted on the, [inaudible] they would accept it only if it came to them first, then we could put it on the [inaudible].

Pam Alexander: What kind of print media are you talking about? Like magazines, newspapers?

M: Talking about trade journals.

Pam Alexander: Oh, trade journals. Did...

Jamie O'Donnell: We're not having that experience at all with the Quick Tutors product, with the Windows 95 tutors product. It was on-line in a lot of places as the product launch, as most of the computer trades are now working on reviews as they do round-ups about various health products for '95.

M: We're not Microsoft.

Jamie O'Donnell: Right. We'll it's not a Microsoft product.

Pam Alexander: No.

Jamie O'Donnell: It's a small start-up company product. So, so we aren't, we haven't been coming across that particular issue as we, as we go to the print media second.

Pam Alexander: Jamie, one other point just to keep in mind, is just the whole timing of it. I mean, all the lead times. If you're dealing with a trade monthly, you might want to hold-off until you've given sort of advanced briefings if it's a new story to people, before you actually put it on your Web site, or do any sort of on-line issue. I mean, whether you're Microsoft or not, you might get less interest if they feel like they've been scooped by, you know, the dailies. So...

M: [inaudible] nobody on the on-line, the Internet [inaudible] to the print media.

Tanya Mazarowski: Another question?

M: A follow-up on that other one. [inaudible] is driving me crazy. [inaudible].

Pam Alexander: I think things are going to be technical. There are going to be vendors who are going to have directory services. I mean, we're really at the birth of all of this, and whether it's AT&T or whether it's Netscape, they're going to partner with people who can do directory

services so that they'll be in the intelligence, where you're not going to have to deal with the kinds of naming, schemes and conventions we deal with now. I mean, that's not going to be overnight, but in the meantime, we're going to have to limp along with that, I think, and just, and sorry I didn't get those names of the Web sites to you guys. I know, I can tell you Ventana's. It's vmedia.com. So but the others, just look up in Yahoo.

Tanya Mazarowski: I'm going to give you all a chance to talk to our panelists off-line kind of, and please enjoy your fifteen minute break, and then we'll come back for Russ Robinson with CompuServe.

PUBLIC RELATIONS A CORPORATE VIEW OF PUBLIC RELATIONS AND THE INTERNET

MODERATOR

Tanya Mazarowski
Public Relations Director, Mecklermedia

SPEAKER

Russ Robinson
Director of Public Relations, CompuServe, Inc.

Tanya Mazarowski: I crossed paths with Russ for the first time in Las Vegas for a Comdex event, and we became friends through a mutual appreciation of Willie Nelson and chili. He began his career as a radio announcer in South Carolina while he was a student at the University of South Carolina; from there he went to the Boston Bureau of the Associated Press where he was a broadcast writer and regional editor.

Lured by hi-tech writing and reporting, he moved to Florida in the early 70s where he became an aerospace reporter and editor for the Gannett *Today* newspaper near Kennedy Space Center. The *Today* newspaper is a prototype for the *USA Today* paper that we all know. Russ spent his stint in Florida's west coast as a political reporter for the *Tampa Tribune* before joining the *Baltimore Sun* in 1979, where he once again was drawn into the hi-tech world.

In 1984 he became a magazine editor for IBM in White Plains, New York. During his career at IBM he managed communications, community relations, press relations and publications in Manassas, Virginia, Gaithersburg, Maryland, and Triangle Park, North Carolina. Just before leaving IBM in 1994 he was Executive Communications Advisor to the General Manager of IBM's Networking Software Division.

Since joining CompuServe a year ago, he's seen his company almost double in size and his public relations staff quintuple in people — that's a five-fold increase in the size of the department. And if that's not enough to keep him busy, he rebuilds and rides motorcycles in his spare time. I introduce Russ Robinson.

Russ Robinson: Thank you, Tanya. Oh, well... Listen. I have no foils. I have no slides. I have no PowerPoint. If I can't hold you with what I have to say you're going to be bored anyway, and that's not going to do me any good; so I'm going to talk to you professional-to-professional. Now, I was here a little bit earlier, so I kind of have a pretty good sense of who you are. I'm going to move around a little bit while I talk, because that's just who I am.

Let's start with some basic assumptions. I assume that you know what the Internet is, that you know what the WorldWide Web is, and that you know what Home Pages are. If you don't know that, this is not the place to learn it. Well, I take that back; go downstairs, and you can learn an awful lot about it. But this seminar is not the place to learn it. You have to get the equipment. You have to get on-line. You have to spend the time and effort to learn what this medium is all about, and I cannot teach it to you in thirty minutes. Nobody can. You've got to learn it yourself.

It also assumes some degree of computer literacy. I can't imagine anyone in our business these days who doesn't use a computer, but I still run across them. I run across reporters writing about us who are using DOS machines from God-knows-when — 286 machines — so there still are a lot of people out there who are not really computer literate and who really aren't up to speed with the technology. You've got to get up to speed with the technology, and the best machine you can buy is the machine you should buy. The higher the modem speed, the better.

[Let me start by going over] some basic premises. Cyberspace is a new medium. I'm going to tell you some things that we've done, and the way I've arranged this is that I'm going to talk about ten things that we've actually done at CompuServe, and then I'm going to try to weave into that ten things that you shouldn't do because they're just going to get you in trouble. And this is the voice of experience speaking.

The Internet really is a loose network of thousands and thousands of servers and millions and millions of PCs; so what we have is a tremendous source of information out there, and a tremendous source of interactivity.

[I want to mention] usage figures. Who's out there? It depends on who you believe; the figures vary from five million to thirty million people, and the truth is probably somewhere in between. I know that at CompuServe we have almost four million members, and AOL has almost four million members, and Prodigy is sitting there at a million. That's close to ten million right there, so in my mind you know it's got to be a lot more than five million... But it is an emerging media.

Who are the people who are on-line? About 85% of them are in North America. That's good news for us, because most of us work in North America and most of our markets are in North America. That comes out of a Georgia Tech survey. Most users are males; their average age is about 35, they are professional, highly-educated, and their average income is about \$70,000. This is not a cross-section of middle America, but it's changing. It's changing every day.

The PC industry believes and hopes — and I do too — that they are getting ready to enter one of the largest Christmas seasons ever for the sale of PCs. And that's good for all of us, because — I forget how the ratio goes, but the value of the network increases geometrically according to the number of people who use it. One telephone is useless, two is twice as good; but [if you have] a thousand or a hundred thousand people on the telephone, then you have a network, then it becomes useful and then it's a real tool. So we are growing.

Seven to nine percent of the U.S. population is currently on-line. It's a tremendous market out there, and it's going to keep growing.

InterAd Monthly predicts that by the turn of the century on-line marketing will be a billion dollar business. I don't know how big it is right now, but it's big. It's foolish to ignore this tool, because it's a tremendously powerful tool. You don't think it's foolish? Do you remember a company called Intel? Okay. Remember how they had a little problem with the Pentium chip? That started at Lynchburg College. I'm sure it's a great college, but it's not exactly MIT. This professor, on a pretty innocuous bulletin board, posted a little problem he was having with his calculations, and it didn't take long for that to spread across the entire Internet. Intel at first tried to ignore it; but in the end, Andy Grove, the President of Intel, ended up issuing a public apology. They just misread it. [That shows how the Internet] is a tremendously powerful tool.

But it's totally unorganized; "global anarchy" is how you often hear it described. There's a loud voice to the silent majority, and it also gives us a loud voice.

The things that I'm going to tell you — if we look back three years from now, they'll probably look about as primitive as the vacuum tube, because this is an emerging medium and it's only limited by our imaginations. Now, remember one thing about the vacuum tube; it's big and it's bulky, but it worked. So these things that I'm going to tell you have worked for us, and hopefully you'll walk away with something that will work for you.

One — and there are ten of them, so you'll know when I'm getting near the end — through the Internet or an on-line service, you can communicate directly with your clients or consumers. It's a tremendous tool; no more mail, no more telephone calls. You write it down, and everyone understands. You can go on-line to do surveys of your clients. You give an e-mail address when you issue your products, and they can get back in-touch with you.

We recently did a promotion with radio stations where we were giving radio stations free accounts. And we said, "We'll give you a free account so that all of your listeners can reach you on e-mail, and all we want out of it is for you to mention that address five times during drive-time on every single day." When you stop and think about that, it sounds like nothing for them. But every time they're doing wsyx@compuserve.com, we get the CompuServe name mentioned. If you establish a WorldWide Web site, every time you give out that address you'll get your name mentioned. Mindshare — that's what it's all about.

We put Bob Massey's letter to customers or members on-line, on our WorldWide Web page, so that he can speak directly to them. And we build into that a feedback mechanism, so that they can speak directly to him. I've offered to answer those letters for him; he gets a lot of them. But he really does answer them personally, because it really gives him a feel for what people are thinking about our service out in the real world.

That brings us to point two, which is e-mail. E-mail, in my opinion, is the most powerful tool in cyberspace, and it's also the most dangerous. Now we've covered both points here.

I think Pam said earlier, "How many of you have been pitching to reporters on-line?" Well, I know we do it. But I also know that if all of us do it, none of us will be effective. You have to be very careful with e-mail.

In July we did a survey. We had 600 reporters we deal with on a regular basis on our list, and we sent out a survey to all of them, some of them on-line, if we knew their e-mail addresses, and some of them hard copy, and we said, "Okay, guys. We want to know two things. What information do you want, and how do you want to get it?" Basically, we were asking them for permission to use e-mail to send them stuff, because if you send people stuff without their permission on e-mail, you're creating a problem for them and they're not going to appreciate it. And it's very easy to very quickly alienate a reporter doing that.

I'm going to tell you the truth. I get 120 e-mail messages a day, and with about a third of those I see who they're from and I hit that "delete" button. They're gone. You don't want to be one of the people that happens to.

So you have to use e-mail very judiciously. You have to write tight, and you don't send all the information the first time. It's just got to be a quick note that says, "Mr. Sandburg, are you interested in a story on XYZ? If so, hit the reply button and tell me you want the release, or that you want a letter from Bob Massey, my CEO, and he'll tell you about it." [You want to write] little things, quick notes just get their attention. If he says, "No," move onto the next person on your list. If you're trying to sell an exclusive, you can do a wide area distribution if you want to, but we have found that what e-mail allows us to do is target things. That's another one of its strengths, that you can target things. If this guy says, "No," it is very easy for us to redo that e-mail note and redo that material and send it out to the next person on the list.

Today we are issuing fewer news releases at CompuServe, but I hope that you guys are seeing more news stories about us. That's because we're targeting. Part of that survey allowed us to break down the different things that we do into areas in which journalists would be interested.

The guy over at the *Wall Street Journal* really doesn't care an awful lot about us bringing Tom Hanks on-line; so we've got an entertainment list, an e-mail list [for people who would want information on entertainment]. Then we've got a business list. We've got a finance list. We've got — we've broken it down into as many different categories as we can so that we can target what people want. It increases the odds that we're going to give them something they want. We don't send everything to everybody.

It's also very important, as I mentioned earlier, for you to understand who is e-mail savvy and who is not. There are folks out there that don't use it. We'll give a journalist, if he can prove his credentials, a sponsored account, which means he doesn't have to pay for it.

We'll send him messages, messages, messages, and finally place a phone call. "Oh, yeah, yeah. I just never check my e-mail." They're not very effective if they're not reading it. So you need to understand who's going to read the e-mail and who isn't, and then target your releases.

All of us know, as professionals, that over and over again editors and writers tell us, "Nothing irritates me more than to get something that neither my publication or I am interested in. Don't send it to me."

When you're using e-mail, generally most of the services will allow you to put a little signature block at the end of your e-mail message, and you can use that signature block to subtly sell yourself and your message. Now, don't be too overt; I mean, these guys aren't dumb, so be very careful. But use that block to tell them who you are, to tell them what your service is all about, and to slip in a little message that may subliminally slip in.

And remember to check your e-mail regularly. In most of the services you have to log-off in order for your e-mail to be updated, so you've got to go on and off several times a day to make sure that you're seeing all the stuff that's in there to you.

As I said earlier, I get at least 120 e-mail messages a day. It can become a beast, so you've got to manage it very carefully.

You can also use e-mail between you and your clients. I'm in the PR business, but we also use a PR firm, and we can very quickly exchange documents. We can review PR plans. They come in to me, I can revise them, I can send them back, and we can very quickly come to an agreement on what we're going to do, [and do this in a way that's] better than we ever have been able to do before. So keep in mind that not only can you talk to the journalists, you can talk to your clients.

Number four. This is one of my favorites. What a tremendous source of information is out there... Cyberspace — good grief, it's all there. You can spend hours out there and not even toast the tip of the iceberg. It's amazing. That also allows you to monitor what people are saying about your industry and about your company.

What you've got to do is go out and identify those newsgroups or those forums that concern your company and then watch, participate, listen. See where the industry is going, what they're saying about you. Be very wary about responding, or getting defensive or being dragged into a flame war; but you can often foresee problems by paying attention to what I'm going to [identify] as "troublemakers," and what they are saying about you out in cyberspace. And, of course, if you can monitor your industry you can also monitor your competitors.

If you have access to the PR news wire you can read all their press releases, the moment they come out. You can read the Business Wire, AP, Reuters, they're all on-line. All of the major services have some sort of search function that allows you to set up folders and pick the kinds of stories that you want, and then they'll build you your own newspaper, so to speak. The *Wall Street Journal* has a special service that allows you to get a customized edition of the *Wall Street Journal*. You can even get stories that haven't even been printed, because not everything that those guys write makes it into the newspaper. You can just get all sorts of intelligence and information out there.

Again — and I mentioned this before, but it bears mentioning again — cyberspace gives a very loud voice to small groups of people. So you, as you become more adept at it, will learn to deal with it; but you've got to remember, don't overreact to somebody who is critical of you, because it's very easy to do, and in the long run you can only lose. And if you say something in writing that you [think] later you shouldn't have said, it's too late, because once they put it out there for thirty million to see on 900 different bulletin boards [it's too late]. And that really happens.

Number five. You can monitor your own effectiveness as public relations people through cyberspace. Those folders that I talked about earlier — did you pitch a story

yesterday? Did anybody pick it up? Do you want to send a copy of it real quickly up to the CEO's office, so that he'll know you're doing something for him? You know, that's a CEO's biggest complaint: "We don't get enough good press." I see some people smiling out there; believe me, I hear it often enough. But it allows you to immediately monitor the press, copy those stories, and send it to him in e-mail to document what you're doing for him.

Research. Do you need demographics, magazine articles, government statistics? They're all on-line.

Speech writing. Before I came here, I went into CompuServe's PR and marketing forum, and in thirty minutes I downloaded thirty-five articles on PR and cyberspace. And interestingly enough, I found most of those people wanted to sell me something. You know, "Here's a little taste. How about buying the book?" But I still got a few good points out of those articles. I also downloaded a guide on comedy writing techniques, but unfortunately for you guys I didn't incorporate any of that into this pitch. See? If you had gone on-line and listened to all of that stuff, you wouldn't have had to sit through this seminar today. You could just read those documents at your leisure.

[This is the] seventh point, if you're keeping score. There is a professional community on-line that has a unique sense of sharing and cooperation, where you can talk to other professionals in a way that you couldn't talk to them at any other time. You can go into private conferences, you can ask them about things that worked for them, you can ask them what they think about an idea, and you can participate in issues debates involving our profession.

I'll give you a "for instance." About three weeks ago CompuServe decided to run a little ad, you know, just to take a little jab at Microsoft, and it had a road construction sign. It said, "Under Construction. So this is the Microsoft network?" I kind of liked it. We wanted to place that in seven key markets, and of course every newspaper in the country is going to accept \$13,000 for a full page ad — except one, the *Seattle Post Intelligencer*. Well, you know me, that's the best thing they can do for me. The *Post Intelligencer* wouldn't run the ad. Okay, save \$13,000, get the PR anyway — I don't care. But on-line in our forum, which has 30,000 members, there erupted this tremendous debate about what had happened. Did the *Post Intelligencer* have a right to do that? Was CompuServe right to exploit the situation? But, hey, I got on-line, I answered notes, and for about two weeks I participated in this debate, and it was great fun. It expanded everybody's mind, but more than that there were journalists in there, and I was debating with them, and what we did is we captured mindshare. People who were ignoring us in the past were now debating whether we were doing the right thing or not. I don't care whether they thought we were doing the right thing or not, as long as they don't ignore us. I had a number of friends on there that went into private conferences and said, "Can't you find somebody else who won't print your ads?" So anyway...

Another thing that you can do, and they alluded to it a little bit earlier, is that you can establish Home Pages for yourself and for your clients, where anybody going onto the Net can get some very basic information.

Our Home Page, for instance, has all of our news releases, bios on our execs, photos, and we have logos on-line that we will give permission to people to reproduce, if for some reason they're writing a story about us and they want to do that. It's a repository of information.

Now, two caveats. First of all, it's got to be interesting enough so that people will go to it. What the folks say to me is, "How am I going to do that? How am I going to build this Home Page?" I say something that we PR professionals often hear: "You need professional help."

So if you want to build a Home Page, go to a provider and get some help, because this designer over here who does a great job building brochures for you may not necessarily do so

well on-line. And you certainly don't want to go out and buy a bunch of servers to support your Page, so you need an access provider, and there's a whole subculture there that you're going to need to deal with. So get some professional help; in the long run it will cost you a lot less than it will to try to do it all yourself.

How do you get people to visit it? It has to be interesting. It has to be listed in some directories. There are a number of publications that often have hot new Home Pages, and there are a number of directories out there that you can get listed in. Or you can do something like we did; we wanted to get people on our Home Page, so we sponsored the "Internet Scavenger Hunt." We went out and we got a whole bunch of partners, and we said, "Okay, here's the deal. All you Internet surfers out there, if you go on and participate and go into all these different Pages that our co-sponsors are involved in, and you dig up these clues, and you get them right, we'll enter you into the drawing; and if you're the lucky individual from Comdex, we'll give you a new car." I wanted to give away a Corvette; I think we're down to a Corolla. But still it's a car, you know. And it's working pretty good. We're having tremendous participation. And all of a sudden this one is drawing to a close, of course, because Comdex is coming up in November, and we have folks coming to us and saying, "When's your next promotion? Man, we never got so many hits on our Home Page. Man, this is great." So we don't put the clues right on the first Home Page; no, you've got to dig down in there so you get a lot of messages before you get to the clue.

Now, I'm going to tell you about something we haven't done yet, but we're getting ready to do, and it was alluded to a little bit earlier as we talked about audio and video technology coming on-line on the Internet. We're getting really excited about the possibility of doing an Internet live news conference with video and motion. You know what's holding us back? Those damn reporters again — they don't have the machine so that they can watch it. But as soon as we feel that technology has reached the stage where all the reporters' machines — or a large group of reporters' machines — are up to speed, we can actually host a press conference with our CEO right on-line. They can see him, they can talk to him, they can ask him questions and they don't even have to leave their desks. It's a reporter's dream, if you ask me.

Now, the last thing. This is number ten. If you decide to go on-line, and if you decide to use cyberspace, you have to promote yourself. Put your Internet address — or your CompuServe account, if you so choose to use that service — put that on your business cards, put that on your brochures, get your clients involved. Tell them to promote themselves. It gives you a hi-tech image. It shows you're with-it. And you'll be surprised at some of the things that you will get back.

Now, there's some problems that you should be familiar with, and the level varies greatly here, so if you don't understand what flaming is I'm going to tell you. It's a nasty e-mail. It's real easy. You know, for some reason, people will write things to other people that they would never say to them face-to-face. We all know it's true, right? Don't get involved in flaming. Don't get flamed. Don't over-react if somebody sends you a nasty e-mail. I'm guilty of it, I admit it, and every time I have wished I hadn't done it.

Open solicitation, if you are too blatant about it, will get you flamed. And as PR professionals, if you send out a note that is poorly written, or has poor grammar or misspellings in it, you will just get hosed. So don't do that.

Another thing that will get you flamed is "spamming." Spamming is posting messages to everybody, to every bulletin board you can possibly identify. That is a no-no in netiquette; do not do that. Your mailbox will fill up so quickly you'll spend the rest of your life emptying it, and your provider may cancel your access. Spamming is a no-no. Don't spam.

“Spoofing” is one of the latest things that has come to light that is causing some problems. Spoofing is sending out a general note that looks like it came from somebody else. For instance, somebody could send a note to some of our employees and make it look like it came from me, and then I’m up in the CEO’s office explaining, “Well, no, I didn’t send a note out there. No, sir, I didn’t do that.” So you have to be very careful, and you have to be aware of those kinds of things. You can usually track back where a spoof comes from, but you have to work through the different providers in order to do that.

If you decide you want to get on into cyberspace, if you decide that you can use this medium, you’ve got to invest some time, some energy and some money. Go out, visit some newsgroups, pay attention, see what’s going on, and read the “frequently asked questions.” You know, a program’s greatest frustration is that it can’t get anybody to read the manual. All the directions are there, regardless of how well they’re written. They’re there, and if you just read the manual it will solve a lot of your problems. So go out and pay attention.

Secondly, all of the on-line services will give you some free time on-line. Get on-line with all of them for a month. Not just CompuServe — AOL, Prodigy, anybody else? Maybe even the Microsoft Network. Don’t stay on-line with them, but get on-line with them, see what they have to offer, and then pick two of them to stay with. What you’ll discover is that all of them have different things to offer, and if you pick one you really are limiting yourself and the things that you’re exposed to. So get on-line, take the free month, look at all of them, explore, and then pick a couple to stay with; for ten bucks a month you can’t beat it. You spend more than that in postage in a day.

Explore the Net. Most of the services now have integrated browsers, which means it just automatically takes you out to the Net when you want to see something. And when you don’t, it brings you right back into the on-line service, so it’s all seamless. It makes it real easy for you, and that’s the trick — to make it real easy for you.

Lurk and learn, and have some fun.

Those are the ten tips, and the ten caveats, and almost everybody’s awake. Thank you.

I always say I’ll be happy to answer questions, and if I don’t know the answer I’ll make something up, so... I either did real good or real bad. Yes.

M: Is your on-line news conference [inaudible] individuals had seen the news conference, what would be the purpose of the press before you?

Russ Robinson: We can limit who we allow into the news conference. We go into a closed area, and we only allow certain IDs into it. But that’s a very good point; it also points to something Pam Alexander — I’m sorry, I think it was Jim — said earlier, in that you almost get into the point of being a competing medium. We can take our message directly to our customers, and that’s exactly what we’re doing with things like Bob Massey’s newsletter to our members. The people that we can’t reach are the people who aren’t on-line; and remember, only 9% of the people are on-line, so there’s a vast audience out there. We still need the other medium or the other media to reach.

M: When is a closed — what do you mean by a closed [inaudible]?

Russ Robinson: Yes. I can’t speak to the other services, but within CompuServe we can limit access to groups. I invite you to go downstairs, see the CompuServe booth, and pick up one of those diskettes and start exploring. Thank you.

PUBLIC RELATIONS
HOW VENDORS REACH THEIR MASS MARKET DIRECTLY
THROUGH THE INTERNET

MODERATOR

Tanya Mazarowski
Public Relations Director, Mecklermedia

SPEAKER

Daniel Janal
Janal Communications

Tanya Mazarowski: A couple of months ago I was well-settled into my new duties at Mecklermedia, and Ellis Booker, a Senior Editor at *WebWeek*, called me and says, "Hey, I didn't know you knew Dan Janal." And I said, "Oh, Janal. Yeah, he's that guy that wrote that book." Well, I was in the acknowledgments, and I was thrilled to hear about that. Here's our book.

Dan is a professor at UC Berkeley, and the owner of Janal Communications based in Danville, California. He's an experienced marketer, entrepreneur, speaker, and author of *How to Publicize Hi-Tech Products and Services*, *The On-line Marketing Handbook*, and *101 Businesses You Can Start on the Internet*, [which is] coming out in November. I believe advanced copies are available at the Van Nostrand's booth downstairs.

Everyone wants to start a business on the Internet. Dan was on the publicity team that launched America Online, and he serves as an Assistant Sysop to CompuServe's Public Relations and Marketing Forum. He says you don't have to be a computer wizard to use the Internet for public relations and marketing. He's a man who knows that by just saying "thanks" you can make a person's day. Here's Dan Janal.

Daniel Janal: Thank you. Thank you very much. We're going to talk about three important distinctions in dealing with the media and getting your publicity on the Internet. The first, of course, is dealing with the media and how the media uses the Internet. The second is about how PR people can use the media on the Internet, and the third is how you can bypass the media entirely because — hey, man, you have your own printing press on-line. This will be a hands-on session, and you'll get a lot of tips and tricks and a lot of good information that you can put to use right away to help your companies get publicity.

So what we have now — I'm going to be referring to a study several times here. It was sponsored by the Columbia Journalism School, and it's also referred to as the "Ross & Middleberg Report." It has a lot of good information about how reporters use the on-line services to gather information, to access credibility, and how they like to deal with people on-line. You can get your own free copy by going to the J-Forum on CompuServe and looking for the survey, or you can call a phone number for a copy or with questions, and that number is (212)-888-6610. A lot of good information there.

M: J, J-A-Y, Forum?

Daniel Janal: J-Forum, as in "Journalism Forum."

M: Thank you.

Daniel Janal: Okay? Great. Shorthand, that's the actual name of the forum. Okay, let's get started. There's a quote I'd like to use from the report. It says, "What we are witnessing is

nothing less than the birth of a new way to communicate.” The study highlights the fact that the impact [of the Internet] on journalists is real, growing, and must be understood by all of us interested in being communicators. And this helps the journalists in their essential role.

Over the weekend Marvin Kalb of NBC was talking about the Internet, and he basically says that the journalist’s function is to edit reality for the public. On the Internet there are so many different realities that can [be] posted, so it’s up to the journalist to figure out what’s real, what’s false, and to interpret it. The journalist’s role will never go away; but in the meantime PR people can help to influence journalists so that their products get covered and their companies get covered as well.

But there’s a different edge to journalism on the Internet. [Brock Meeks], who has his own newsletter and has a column in one of the weekly magazines on the Internet, says, “Way-new journalism, by its nature, relies on making itself stand out from the mind-numbing morass of information that flows through the Net.” To stand out takes a certain arrogance, if you will, but it damn well better be what I call “bullet-proof” arrogance. By definition this is a bedrock belief that your facts are accurate and that you’ve not given any part of your story the short shrift. And that’s real important, because [Brock Meeks] was the first computer journalist in cyberspace sued for libel. He won the case, but he learned a few lessons about checking out sources and checking out stories in the process.

The Columbia Journalism School report has a very interesting statistic; it shows that there are lots and lots of reporters on-line. These are traditional reporters from daily newspapers, magazines and consumer publications — it’s not just the technology press. They sent out over 6,000 surveys to business magazines and such. They got back 725 responses from daily newspapers, and when you consider that there are about 1600 daily newspapers in the country, that’s a pretty good percentage of representation. Sixteen percent of those reporters use on-line services every single day; thirty-three percent use it once a week; and fifty percent use it once a month. And what do they do when they’re on-line? A number of things.

First, they can go to PR Newswire and check out company information. You can go down to the PR Newswire booth downstairs, or the Businesswire booth outside this hall. They both have very interesting services where they’ll distribute your press releases to reporters, [which is] what they’ve always done through traditional sources. Now you can put your press releases on-line so reporters can go there, do keyword searches on your company or on your topic, and reporters can find your latest press releases. PR Newswire also has a service called *News On-Call*, where you can actually have your press releases listed for a full year for a fee so it won’t just scroll off the system at the end of the day. So there are a lot of interesting things that both companies are doing to get your press releases out to the public.

One of the cool things about these two services is that anyone can reach those services — and we’re talking about consumers — so if reporters don’t write about your press release, consumers can still find it by doing a keyword search or a company search.

Reporters also look at Home Pages for news. For instance, I was doing a report a few weeks ago and I went to the IBM Home Page to find out what they were doing, because I figure they must have a pretty good site; and on the very first page was the announcement of IBM buying Lotus, and it was official. And that was on a Sunday. Now, you have to remember that a Sunday is not your normal news day. You don’t really listen to the news [on the] radio, and the TV doesn’t have a whole lot of news reports; you’re watching football and stuff like that. By going to the Home Page you’re able to get the news out to everyone immediately, and so it was a very good move on IBM’s part.

Another way that reporters can find information is to do keyword searches through companies that link to all the Home Pages, like *InfoSeek* as well as the more traditional *Yahoo* and *WebCrawler* and such like that. They also look for controversy, and they can find this by

going to newsgroups. It's real important for you to monitor controversy on-line. And you think, "Gee, there are 18,000 newsgroups, how are we going to do this? You know, it would take forever."

Well, there are a number of companies that are starting to monitor this service for you for a fee. For instance, you can go to the *Deja News* site, which is up here; this is a service that was bought out by AOL, who knew a good thing when they saw it. You type in a query for, say, "Intel." Well, Intel had a few problems, and it will automatically go through all the newsgroups for many, many months previous, up to today, and find every occurrence of the word "Intel." So in this way you can find out if people are having a problem with your product or are saying nasty things, or even had realistic questions like, "How do I use your product more effectively?" You can also legitimately add information to those newsgroups and tell people what's going on. So it's a very valuable service.

Are we getting a response here? Well, we are seeing an ad, so we know that part of *Deja News* works. Trust me, it works, it's a good service. You should all look at it at least once a day to monitor what people are saying about your company.

Here's a list of the first 30 hits for Intel; you can even see a few of the keywords so you can find out what was being said, and the name of the newsgroup itself, so you can find out where it's being populated. So it's a very, very good service.

Reporters also use... Okay, there's another way. You can actually subscribe to a service called *eWatch* that's also done by PR Newswire, and here you can do a report for, say, "Travel," and it will show you the number of news articles — that's UseNet newsgroup articles — written about your company or your industry or your keyword, and they also summarize the information as well. So that's another really cool tool that you can use to find out what the world is saying about you.

Reporters also use the Internet to find stories and actually pitch stories on-line. Here's a newsgroup posting by [Kim Baine], who is writing an article for a magazine. she says, "I'm writing an article on demonstrating a return for your Internet investment for a national publication, and I would like to discuss it with both company and agency hi-tech professionals. So if you happen to fit in that mode you can write me later, and I'll give you the address here." So if you look in newsgroups you'll find those [types of] postings from reporters all over the place.

There's also a neat new service called *ProfNet*, which is basically a free service for reporters that lets them post query letters on-line through this service. The subscribers to this service, at this point in time, are university public information officers, so someone could post a note saying, "Hey, I'm doing an article about music. If anyone at your university is doing research on musical instruments of the 1600's, please have them give me a call." Well, there are hundreds of these postings, from consumer to hi-tech to everything.

They are going to expand this service so that it's not just PR professionals at universities and colleges, but PR professionals at any kind of company. And this service is being used by a lot of reporters. Jonathan [inaudible] with *The New York Times* says, "*ProfNet* is the Global Village's matchmaking service for academic and news organizations." *News Day* says, "Experts to the left of me, experts to the right of me, experts on the phone, experts on the fax. When reporters are desperate for experts on esoteric topics, which is all the time, all we have to do is call, fax, or e-mail *ProfNet*." There are also testimonials from *Fortune* and *The Chicago Tribune*. And these are the consumer reporters, these are not the hi-tech reporters. So check it out, use it to keep up to date, and when they actually do go live to have consumer and technology companies [involved] you definitely want to become a subscriber so you can read what reporters are posting.

There are also a number of resources for the media on-line, like the National Press Club, and [Nando News], which has hundreds of links to daily newspapers. You can check them out as well to see what's going on. And there's also the J-Forum on CompuServe, which we talked about briefly, where the journalism report is being held. That has 35,000 members, and they're always asking questions of each other, and some of those are pitches. So in that way you can start to enter into conversations with these reporters on a collegial basis and start to build a rapport with them.

Now, reporters are doing a lot of interesting things on-line that you wouldn't think of. For instance, some of them are printing their editorial calendars on-line. Greg [inaudible] at *PC Week* — he runs the "Buyer's Guide" section — has his editorial calendar on-line. He tells you, "Here's what I'm interested in. If you can help me, get in touch." Other reporters are printing their own newsletters. Doug Millison, the editor of *Morph's Outpost*, has an issue of *Morph On-line* that he publishes everyday, and there's a lot of good information that will keep you up to date on the industry. You'll also know what he's talking about. [Brock Meeks] and other people do their own newsletters, and I think you'll see a lot of other reporters doing it as well. It's just a fun thing for them. I don't know how they're getting paid or whatever, but they're doing it, and it's another avenue for you to get exposure for your company or for your clients.

Other reporters have their own personal Home Pages, like [Gina Smith and Dave Frobridge] of *PC Week*, and basically they list the current articles they're working on, and they have columns, they have gossip, and they have their editorial calendars. So again, it's another way for you to get your company into the media.

More and more publications are going on-line, as you know. All the Ziff Davis publications are on-line; but there are also a lot of daily newspapers on-line, from *The Los Angeles Times* to *The San Jose Mercury News* to *The New York Times*. You know, the Columbia Report says that 75 percent of the companies surveyed expect to have an on-line version of their publication; that's three out of every four of every daily newspaper and magazine that you see. So it's becoming an on-line world, and you want to deal with that world effectively.

So, as we end Part I the summary and conclusion is that journalists are on-line, and they like to use on-line, they like getting news on-line, and they like interacting with PR people and company officials on-line, if you know how to do it correctly. So let's look at how to use the media correctly.

Columbia says, "Although no one can say where it all will lead, it is safe to say that something momentous is under way. As electronic forms of communication grow in popularity and in use, public relations practitioners must not only adapt to new technologies, but embrace them. For public relations practitioners it means an important new dimension has been added to the profession. While personal media relations skills will remain paramount, an entirely new set of writing and communication skills will be needed. Indeed, it is clear that the rules of the game are changing right before our eyes." So the next 15 minutes or so, let's talk about what some of those new rules are.

I see two cardinal rules. The first is: "Be a resource, not a pest." If you pitch a letter to the reporter and he doesn't get back to you, he's not interested. Don't keep on pestering him with other notes, and say, "Hey, you didn't get back to me. Did you get my press release?" They'll kill you. The second says you have to write for the new media, not the old media. There are whole bunch of new rules, and we'll go through those step by step in another minute.

Let's talk about how to build rapport on-line first, and a lot of this is PR 101. You find the right story, pitch it to the right reporter, and make sure it passes the "Who Cares" test. If no one cares about this, the reporter won't either. If only your company president cares about this, you know it's going to fall flat in your face. Also, you must have accurate information and complete information. This is something that reporters know about, where you only tell one

side of the story. Well, on the Internet it's real easy to find the other side of the story and to fill in the blanks; so if you don't tell the reporters what's going on they'll find it, and you'll lose some of your credibility along the way.

Also, in the new PR you need to identify yourself as a company source. Think about this: you're on a newsgroup, and you see a posting by some consumer, and he says, "I like your product," or "I don't like your product," and you respond. Well, a lot of other normal people could be responding too, and reporters do look at those things. That's how the Intel debacle was discovered. That's how Pack-Rat errors and bugs were discovered. Reporters are looking at this stuff all the time. But if you respond to one of these postings, just simply say, "I work for the company." It makes all the difference, because the reporter knows to call you, and they can trust you, they can establish a relationship with you. But if you just post it normally, which is your first inclination, something is missing, because then they think you're trying to fool the public. It's a subtle thing, but that's what happens on-line. On-line is a very, very subtle medium.

So what you need to do is follow these five rules from a friend of mine, [Skye Catonin at Neahouse, Ryan, and Hallor]. Is Skye here? Oh, I thought she was going to make it here. Okay, cool. Skye was actually in my class at Berkeley, and then she was working for [Neahouse], and she's really emerged as one of the superstars in on-line PR. I mean, if [John Barody] at *Business Week* writes about somebody, chances are it's one of Skye's clients. She's real good. These are some of her rules.

One, become friends with reporters. Build relationships with reporters as people, not as editors. You have to get to them and say, "We're both passionate about the industry. We can both make this work. I'm important to you. You're important to me. Let's be friends." That's real important, because a lot of PR people take the attitude that, you know, "I have a job to do, and I've got to talk to this, and I've got to make these phone calls..." That's not the attitude to have when you're dealing with on-line reporters. You have to come at it from a position of worth and say, "I have something valuable," and in that way you can make 500 phone calls, too, because you know that you have something of use. The good reporters respect PR people, because they know that they have information that will help them write their stories. And as time goes by you develop trust with them, and they trust you as a real person. So that helps to get a lot of credibility for all of your clients and all of your products.

The ultimate goal in this is not just to pitch, pitch, pitch, but to develop a relationship so that when they are working on a story their first inclination is to call you and not your competitors. Wait for the phone to ring, or wait for the e-mail to ring; if they're working on something, they'll call you because you have credibility with them.

So there are a number of rules of etiquette to follow in this. First, do they want e-mail? Do they want a phone call? Do they want faxes? Every reporter — are there reporters in this room? One or two, okay. I know this is being recorded, but there are a lot of reporters, frankly, who are prima donnas. I've been on a lot of PR panels where we have five PR people, five reporters up here, and one says, "Call me, don't send me stuff, I don't read stuff." The next person says, "Send me stuff, I read everything. Don't call me, it's a waste of time." The next person says, "E-mail me something. If it's on paper, I don't want to deal with it." The next person says, "I don't have an e-mail account, don't send me e-mail," or, "I only want to deal with e-mail with consumers, not with PR people." Every one of them is a prima donna. Unfortunately, we have to deal with them on their own level.

MediaMap has a very good service where they tell you which technology reporter wants to be contacted in which way. They also have a relationship with PR Newswire where you can send them your media list, and they will know by their database who likes to get material in which manner, and they'll fax to the people that want to get faxed, and they'll e-mail to the people who want to get e-mailed to.

Another word about e-mail boxes. A lot of reporters have several different e-mail boxes, and some are for internal company stuff, and some are just for consumers, so you have to figure out — we have to ask them which box they want your stuff sent to. And again, this does a lot to build relationships with reporters, and a lot to minimize the downside.

Also, don't send a massive list as your PR distribution method. It's okay to send your press release to 200 reporters, but they should be sent individually. If you use the form box that basically says, "Mail to these 200 people that I've targeted," they will have to scroll through seven opening screens listing everyone else's address before they actually get to your message. Nothing will annoy them faster. So send your messages individually; it takes maybe 13 seconds to address a piece of e-mail. It's worth the time investment.

Also, be sure you don't use the reader feedback e-mail number listed as the letters to the editor. That does not go to reporters, it goes to the letters to the editor person, and they don't forward it to other people. So deal directly with the editor that you want.

The new writing style for e-mail is much, much different than what you're used to. It's a style that's much more conversational and less businesslike in tone than the traditional [style], and the length is one screen, not even a page — we're talking about three paragraphs, if you want to get reporters' attention.

The first step in getting their attention is to write a headline that really grabs them. You have to breathe life into the message. You can't say something like, "Virtual Vineyards Data Test of Cybercash." It might be a good headline normally, or a fairly decent headline normally, but on-line it dies. You want to grab their attention, so you'd use something like, "Are you a wine whiz?" That gets them to open up the e-mail.

So you want to get their attention, but you don't want to trick them. So don't have a headline of, "Sex", and then as it opens up you say, "Now that I've gotten your attention, let's talk about life insurance." That also will annoy reporters.

A press release looks a lot different on-line, too. The first thing you do is provide a summary of three or four sentences, and then have the details underneath it, or the full press release underneath it. In this way the reporter can see what's going on and then read it if he wants to. Some other people actually just have a one paragraph summary and say, "If you want more information, hit the reply button, and I'll send you the full release of the full press kit." But a lot of the reporters just want the summary first, and work on it from there.

Also, you want to have your contact information at the top and also at the bottom; that way people don't have to scroll through everything. In some cases they might lose the connection, so this is something else that helps reporters with press releases. This is a good idea that I got from [Charles Piso] at PR — PR, that's actually the name of the company, "PR," that's very clever — in New Orleans. He does food PR, and we were talking about people who are not involved in technology using the technology to deal with reporters in an effective manner. So it's really becoming pervasive.

When you send e-mail, some other ideas are that when you're sending pitch letters you can't use the normal stuff that you use in a regular letter, like, "Dear John, I enjoyed meeting you last week at Internet World. As you requested, I am sending you information about our new product." You have to be much more immediate; people don't want that stuff. So you say something like, "We'll be in town next week, let's get together. You can see a demo of our new product."

[Chris Belky] at Phase II Public Relations booked 70% of her immediate tours through e-mail, and she does it in a lot less time than voice-mail. That's real important, because voice-mail is becoming such, such a wasteland. I mean, reporters don't return phone calls anymore; [a return call is something] that's very, very odd, unless you have tremendous rapport with that reporter. And freelancers don't call back because they don't want to pay the long distance

charges. So e-mail is becoming a much preferred way of dealing with reporters in every step of the imagination.

Also, after you're done dealing with reporters on-line you can't ignore the off-line reporters; as [Nola Armijo of the Jonah Group] says, they get most of the hits from their clients emanating from the public, from articles that hit in the traditional media. They did the PR for the Miss America Home Page, and after they got into *USA Today* there were a lot of hits that hit on the Page. So you can't ignore the traditional press, either.

In fact, here's a copy of *USA Today*, and next to the TV listings they have the cyberlistings of which company executives and which stars and which authors are in conference on the on-line services. CompuServe, Internet, and Prodigy. So here's Spinal Tap and Matt Groening, who did the Simpsons cartoons, and the Barbie Twins; so there's everyone from computer guys to Playboy bunnies. And *USA Today* will print all that information.

Okay. So you might be asking, "How do we launch a product on-line?" Nola's Group has a nice, easy, four-step process. One, you find related sites and post to it. They had a Windows 95 launch, and they went to a couple of Windows 95 sites and asked them to print information; some of them did, and others printed hotlinks back to their Home Page, and that was effective.

Second, go to the Web publications and pitch. Some of the more widely read Web publications are *CNet*, *Web Review*, *Hot Wired*, *BuzzNet*, *Geek Girl*, and *Urban Desires*. And these are run by professional staffs, they get thousands of hits a day, and they're well-respected — plus they can get the information on-line a lot faster than magazines can do.

Third, go to the Internet reporters of print publications, like *USA Today*, *Field & Stream*, *Road & Track*, and [make sure] they write it up, that stuff, as well.

And then go to print publications or broadcast publications that cover Internet products, like *Vogue* and *Field & Stream*. They write about the at-fashion Home Pages, and things like that. So it's pretty cool.

There are also a number of ways that PR agencies use the Web to deal with reporters. The Ketchum Kitchen is a good example. Ketchum has a lot of food clients, so they've created an area called the Ketchum Kitchen, at recipe.com, and you can do things like type in ingredients and it will show you recipes. You can also write to "Dear Sandy" and find out how to cook foods better and do things like that. They create an area of a community, which is a great way to build rapport with your customers and reporters, and reporters can see what customers are saying and develop articles and develop case histories and contacts and leads with real people by exploring your Web site.

Your Home Page can also be used to tell people about what you do, like, for instance, the [Neahouse, Ryan, Hallor] Home Page. Editors can find information about clients and breaking news. A lot of agencies — well, not a lot of agencies, but several agencies — you can have information about your clients, you can hotlink to press releases, you could have news that's happening there. You could also have information about your account executives to show what they cover and what their specialties are. If reporters really trust your agency or your company, they'll know exactly who to go to.

So here's a picture of Skye, and you can read all about her. I think this says, on her bio it says, "As a baby, my first words were "Hi", so naturally I would go into Public Relations." And it tells you about her as a person. It's not just, "I went to this school, I went to that school, I majored in this, I worked for this, I did that." You get a real sense of who she is and her dedication to the industry by looking at this kind of a Page. So they get a sense of her as a person, and it breaks the ice. So that's another cool thing you can do.

So as we look at this, there are new ways of writing for the media. It's real simple, it's real direct, it's real easy, and you must do it if you're going to build rapport with reporters.

The third thing I'd like to talk about is the problem that you're going to have in dealing with the media. Up to this point we've talked about the media as your friend and your buddy. You have a story; they like you, they like the story, they print it, and that's great. But there are a number of things that can happen between you and the reporter that don't work out very well; for instance, I've found at least six ways the reporters can mess you up.

One, they can throw away your story. Anyone who's written a press release — has anyone written a press release here and sent it to a reporter? Yeah, let's see a show of hands. How many of you have seen it in print? None of you — not enough of you are raising your hands, you're not playing along, that's not fair. Okay. Most press releases don't see the light of day, we all know this. There's only so much room in a newspaper, and that's what happens.

The next thing that can happen is that you write a 400 word press release announcing your takeover of your competitor. What happens? They print 25 words. Is your public getting the full story? No way.

Third, they could lump your story with others, so now it's not your story anymore. If you're introducing this great new product, but there are six competitors who are doing things that are slightly different, and some of them are even better... That's something else that can hurt you.

Next, they can add damaging quotes from competitors. A lot of reporters don't want single-source stories, so they call another competitor and they downplay your stuff, or they can call an analyst who suddenly puts a new spin on the thing, and now it's turning into a "trend" story.

And, finally, they can unintentionally add errors. And that's happened to all of us.

So what's a company to do? Lots. You can take PR into your own hands and deal directly with your public through the Internet. Some of the ways you can do this is to create your own private mailing list. Create a Home Page, ask people for permission to send them stuff. "If you want to know about the latest news about our company, give us your e-mail address. We'll send you a newsletter every month on-line, and it doesn't cost you anything. You'll find out about our sales and our new products." Real simple. You can do this by talking to your "Webmaster," or talking to your service provider. It's real easy to do.

Second, you can create your own Home Page. Let's go to the Quarterdeck Home Page, please. Okay, great. On your Home Page you can put lots of information; for instance, all of your press releases, your financial information, case histories, free samples, an executive bio, your stock prices, product information, news. Can we go to the Quarterdeck financial or press release Page? Tanya? Yeah, okay, great.

So, at any rate, on the press release Page you list all of your press releases. Quarterdeck happens to list them by month, so you can search on it that way. Then they go month by month, sequentially, in backwards order, and you click on any of those titles. Click on one, it doesn't matter which. So you see the headline, and then it immediately goes to the press release, and here's the media contacts. And as we scroll down, see the hotlinks? You can send a message directly to the PR person, and here's the headline and then the rest of the story as you'd see in a normal press release. And since reporters are coming to your site, and since consumers are coming to your site, you can present it anyway you like, and you can print it as long as you like. You can get as much information as you want, because they've chosen to be there.

You can also use this as a, as a delivery vehicle for reporters. You can have your pictures on-line as well, so reporters can download the pictures and put them into their articles. The Columbia Report says that many newspapers expect to have pictures and text delivered to them through electronic services within the next two years; it's not just becoming an option, in two years' time it will probably become mandatory. By the way, the survey was

done in August, and they said that in five years this is what we want. They did an update to that, and last month they said that majority of reporters now want it in two years. So it's really becoming — reporters are definitely becoming part of the Internet.

Okay. You can also download audio, so now you can have your company executive do speeches, and interested people can download them. And don't fool yourself — a lot of people are interested in this information. I know there might be some reporters here who say, "Who would want to hear the company president talk for twenty minutes about stuff?" Well, if you're a publicly-held company, all the stockbrokers do, all of your investors do. That's very serious information. So, again, you can download pictures or samples of your product so people can start to play with it or look at it, especially if it's a software product.

You can have on-line conferences for your company executives. As we said before, *USA Today* lists them, and all the major on-line services have these conferences, and they love doing conferences, whether they're a technology company or a rock star. So deal with the appropriate person at America Online or CompuServe or Prodigy, or create your own center on the Internet with *WebChat*, or *InternetPhone*, or *VocalTel*, or some of the new software and tools coming out, and set up your own conference.

A number of politicians are using Internet sites to tell people about what they're doing. Every presidential hopeful has one; *The New York Times* had a list of sites for Dole, Buchanan, Lugar, Specter, and on and on and on. I'm going to show you one here, one that I found just before I started. This is actually done by a competing company, and it's actually not a legitimate site, so it's real important to use this as an example.

Let's look at this, because this is actually funny. I've been pretty dry up to this point, so let's have some fun. This is a "Dole for President" Page, and if you look at it, it looks like it was really set up by the Dole pineapple people.

It looks like a real Page. "Welcome to the Bob Dole for President Page. This Page is here to offer information on Dole's candidacy, his views, and what you can do to help." So far it looks totally legitimate. I was on this Page last week, and the headline was, "Wilson endorses Dole." And you can download screen savers and wallpaper of Bob Dole, and learn how to contribute to the campaign, and read his press releases and stuff like that. It really looked like a totally legitimate site.

Now, scroll down a little bit more, Tanya, please. We see a bunch of links. And, again, it looks like a very traditional Page about crime, about drugs, about — let's see, it's "Family Values." Can you click on Family Values, please? This is the first inclination I got that something was wrong. This may take a second to load in, so bear with me here. Please connect... And... It's the Marilyn Monroe Home Page. The Crime Page [from the "Dole for President" site] links to the Microsoft Page. Can you link back, please? Thanks.

At this point I realized that there was something very wrong at the Dole Organization Home Page, and if we go down a little bit more, please... Scroll down, please.

"Flash — Peter Wilson endorses Dole." Again, it looks totally legitimate, except for a few things — like, you say, this is weird. There's biographical information, there are facts, there are press releases and such like that. And right before I went on, a gentleman in the audience — is he still here? Yeah, he's still here. He actually did the legitimate Bob Dole Home Page. And I said, "Hey, your site got hacked!" It turns out that this is another company that's just doing this as a goof, God knows why. They're having a lot fun, and probably confusing lots of people at the same time.

The point is that if you do have a Home Page, check it and make sure that no one is hacking it. Use variations on your name to make sure that no one is setting up a Page that's making fun of you. For instance, look at the Ketchum Kitchen Page; I first typed in things like Ketchum, and that wasn't it at all, it was *recipe.com*, so in this case they didn't have the right to

their own name, or they didn't choose the right to their own name. You might use a company name, like you might have another product. Get the license to both of those names, as both ".com" and as ".org," and even as ".edu", if you think it's necessary, so no one else can steal your name and put stuff like this up there without you thinking about it — or without you knowing about it, rather.

There's a lot of things you can do on the Internet to raise your credibility, to talk to the media, to talk to the public. And as we close, because I know I'm running over a little time here; in short, credibility in cyberspace will be hard to establish. It will also be easy to lose. Remember, it will be easier for reporters and editors to check the validity of on-line material, and as a result they may even penalize companies for accurate but incomplete data.

What we are witness to is nothing less than the birth of a new way to communicate. The study highlights that the impact on journalists is real, growing, and must be understood by all of us interested in being communicators.

So, in summary, the Internet is changing the way reporters work, and PR people must change the way they work with reporters, and the Internet allows companies to bypass the media and deal directly with consumers.

Thank you. Are there any questions? You can applaud, it's okay.

KEYNOTES

JAVA AND THE FUTURE OF NETWORK COMPUTING

INTRODUCTION

Bill Washburn

Senior Vice President for Internet Business Development, Mecklermedia

SPEAKER

Dr. Eric Schmidt

Chief Technology Officer, Corporate Executive Officer, Sun Microsystems, Inc.

Marc Benioff

Senior Vice-President, Oracle

Bill Washburn: Ladies and gentlemen, it's a pleasure to be here with you this morning; and I apologize for the various technical difficulties that we're experiencing in this tent.

I'm struck by the fact that, unlike so many audiences in shows of whatever sort, this seems to be a situation, given perhaps the physical environment and the temperature, that has brought the audience rather closer together to each other than is ordinarily the case. Usually we try and find an extra seat in between us, one person and another; and in this case, anybody we can find, we'll use.

It's certainly exciting to be here in Boston, and I'm grateful to all of the people here in Boston and from around the country, and even from around the world, that have helped make this event possible today and this week.

I hope that you have a great experience here, and that you're successful in accomplishing the things that you're here to accomplish; and if there's any way in which I can help you at all, please know to come and see me.

I'll be in the conference area in the exhibit hall, and with the registration people and the like.

I'd like to say a couple of things in particular. We especially want to thank IBM for bringing the Net to Internet World. I hope you realize that IBM, or if you don't realize it yet that you will soon realize that IBM, is providing six megabits of bandwidth to each of the demonstration areas. I'd like to say that this is a great effort, and I'd like to very much thank IBM for all they've done with respect to the network. Thank you very much! In the days to come, we'll let you know about the activity on the Net from the statistics that they gather.

My children taught me a long time ago that my attempts at humor failed, almost always, and that it is not something that I should ever quit my day job to try and do.

So in that spirit, rather than trying to give you any levity this morning, and recognizing that this is the end of October and that Halloween is upon us, and also given the fact that some of you might even be shivering a bit, I thought it might be appropriate, rather than to humor you, to try and scare you a little bit.

So in that respect, I'd like to mention something that I saw on the Risks list this week. It's respecting...

(Plane going overhead)

Bill Washburn: Airplanes in the Boston area falling out of the sky; indeed!

A company named Deja News, a play, I think, on *deja vu*, Deja News, an Internet archive, that was on the Risk list, commented in terms of the fact that they archive all of the messages posted to UseNet News.

They index, catalog, and provide that information to the Internet community. By the way, if you want their address, <http://dejanews.com>; Deja News.

Anyway, it's become a bit of a concern, because they are able to do things like profile individual user names in terms of what they like and what their interests and likes and dislikes are, and the like. So far they do not, but will soon, start indexing the alt, talk, and society, or soc, news groups as well. They don't today.

In any event, given the capability to index everything in sight backward and certainly forward, I advise you not to be unaware that this is a public environment, and that what you say will be recorded.

This is stuff that is known to all kinds of interested groups, including law-enforcement groups, the National Security Agency, and others in the business community.

And finally, whatever you do, don't post your Social Security number to UseNet News, ladies and gentlemen.

Having taken that little time to make sure that we had the opportunity to experience an airplane or two, I want to introduce to you Eric Schmidt, Chief Technology Officer at Sun Microsystems, and part of the Internet community for a long time. He helped in the development of UNIX with Bill Joy at Berkeley, and ongoing at Sun Microsystems for the last 12 years.

His duties and responsibilities are to continue to investigate and understand the Internet-Web technologies, and to guide the Java programming language development further on into the Internet.

We actually delayed slightly our new Web site so that we could take full advantage of the HotJava browser, and we're certainly excited about it.

Having said that, I'd like to introduce to you, ladies and gentlemen, Eric Schmidt.

Eric Schmidt: I think we have a lot to be proud of.

The latest testimonial is that there are 14 million users of the Web, at least occasional users of the Web. We're all familiar with the growth rates that our industry is now taking, and I think it's pretty incredible.

Think about this show a year ago or six months ago, and how it's exploded from its various venues. Now we're in a tent; moving from site to site with our tent.

The question I want to ask is: is it possible, is it just possible, that we are under-hyping the Internet? Does anyone here believe that?

Well, I do! Of course, I'm biased. And let me tell you why.

You have before you the most significant opportunity since the introduction of the personal computer in 1981; right here! That's pretty exciting. Somebody is going to make a few billion out of that. Maybe it's somebody in this room.

(Of course you can't see my slides, but that's okay. It's okay; I can't see them either. It doesn't matter if you're in the back or the front. This is good. You know, you're supposed to pause during your talks to think about what you're going to say next; and that's 14 seconds, which is plenty of time to think.)

So, the Internet Society estimates that there will be 187 million users on the Internet, 187 million computers, nodes, what have you; and countless others will be in corporate nets.

At that growth rate, there are a lot of estimates that say that, for example, in seven or eight years every human being on the planet will have a home page.

That's kind of a problem, because only one out of five have telephones. But at least in this community, maybe it's more important to have a home page than a telephone.

Now, the good news is that our industry is planning ahead. The successor to the current IP allows for 131 million IP addresses per square meter of the earth's surface! Which is probably a lot. Now, furthermore, you can concatenate addresses, so you can go beyond that, in case we colonize other planets and stuff like that.

Now, we are busy constructing the World Digital Library.

The Web has become the place where all information, because all information is digital, will sit there; and that means every thought, every utterance, every next Thoreau, every library in the world. This has profound implications for all of us.

What's the next Internet explosion? It's probably cellular phones.

Here you have a cellular phone, which has a 40-mips processor in it, which are, in theory at least, continuous connections. The next 100 million IP addresses, remember, we have 131 million per square meter to get to, your next generation will almost certainly be there.

So the underlying premise, which is the world of digitally connected IP addresses and the Web as the world's digital library, is a very, very profound one.

Now, what is the first stage of this new world? I believe that it is the destruction and then construction into a new model of the economics of the software industry.

The reason I say that is that the industry is built on the concept of a software lock-in, an API lock-in. The interface, whether it's Windows or Mac or whatever, is the thing that you're locked to. Just try getting one of those pieces of software running on something with which it's not compatible to what it was compiled to.

We intuitively understand this. In fact, the stock-market valuations of these companies often reflect the value of the architectural lock-in that they have. For us, it's sort of normal; we grew up with it; it's the way the world works. Everyone wants to be the next Windows API or the next lock-in of one kind or another.

But then, something funny happened.

Tim [Burners-Lee], who I consider to be one of the great examples of the technology law of unintended effects, was trying to build a system which allowed him to communicate with his physicist friends.

And Mark Andreessen and other sort of inspired 21-, 22-year-olds, all thought, well, this is neat, it just lacks an user interface, because we're the MTV generation. Right. Makes sense.

You want to use your interface with this data. All of a sudden, a new paradigm begins to take shape, and that new paradigm consists of HTML.

In the last year, many companies have come to see me who have seen the light about HTML. HTML, I assume most of you know, is the format that the pages use when they're displayed on your screen; and so the typical demo, browsing demo, uses the HTML page format.

HTML is going to become the world's user interface, because it's much easier to write a program that spoofs being a Web server. It says, I look like a Web server, but I really am not a Web server; it just shows you its data.

A good example here would be quote.com or *Pathfinder* for those of you who look up stock quotes. You type in the stock quote that you want, and a page comes back to you, and you say, well, that's great, I'm using the Web.

There's no Web there. You're just using HTML as an user interface over the Internet to a server which is giving you the output of its program. Very simple.

Something interesting happened along the way. You see the same user interface, whether it's on Mac or Windows or UNIX. All of a sudden, content is king! If content is king, then all of a sudden that interface lock-in, that architectural lock-in, becomes less important.

I predict that within the next six to nine months virtually all of the software companies represented here, and the rest of the industry, will offer HTML interfaces.

All of the major operating systems vendors, from Microsoft to Apple and Sun and so on and so forth, have all indicated that they are bundling or making generally available Mosaic-, Netscape-, class browsers; and that will become the predominant way in which you all use your data.

Now, what's the problem with this? This is pretty good! Interesting revolution. The content is dead. Nothing happens.

The content is dead because the information is presented on a server, and that information comes to the client, and if you want it to change you have to execute something called CGI binstrips, which go back to the server, get the data, and then you wait again.

That takes a long time; there's a lot of bandwidth involved.

Now, this is an example of another premise that I have, which is that HTML is really the DOS of the 90's. Think about DOS. What were the benefits DOS has? Right? It's a really long list. In 1980, think about DOS. Nothing comes to mind.

In fact, the thing that's funny about DOS is that it has no benefits whatsoever. In DOS I, it even corrupted your files; but it did have one benefit, which is that it was ubiquitous. And the fact that DOS was ubiquitous led many, many people to go fix it.

And the ubiquity of DOS created the opportunity for Windows, created the opportunity for Windows to get fixed, and so on and so forth, and created a whole industry. We're now there. You know the whole story.

So, I believe that HTML, and I mention this notion of the content is dead, will be extended, again by folks in this room as well, to address the many issues that it has. You don't get accurate data representation on the screen and so forth; that will all get taken care of. But the most important thing to do is to figure out a way to use HTML as the next- generation platform for computing, and that's what Java is all about.

The history of Java is that it was designed originally around a small set-top box, and that was back when we thought the set-top-box world was going to sort of take off, and we were, like many people in the industry, very early.

The language itself is a derivative of C++. It's essentially C++ without the guns, knives, and Mace; all right. We went through C++, and we articulated all the things that were in there that we didn't like, and we thought would allow security problems of one kind or another. And by making these changes, we allowed people to write applications which have three important properties.

The first property is that the application can give you interactive content, and you've seen that demo. We'll show you some of the new stuff in just a sec.

The second thing that we do is we run a virus scan. What happens is the Javaprogram comes in, and we do a byte scan. We also then run the Java program in its own interpreted space. We don't let the Java program do many of the classic virus kinds of behaviors.

And finally, because of the way the language was designed, and the virtual machine was implemented, that system is machine-independent.

Therefore, Java programs literally the same binary, in the sense of the job of a virtual machine binary, can run on each of the different platforms.

So one of the consequences of this is that information is the sort of content platform; and now applications and information together can become the new content platform.

Now, Java is to C what the Net was for the microprocessor; and because it's machine-independent and it is safe, you have the properties that you can write programs, and they can be moved around.

Now, the examples that we've used have Java programs sitting on Web servers and moving to the client. There's no reason why you cannot also have Web servers where the program is authored into the Web server.

I believe that ultimately Java will be seen as a replacement for C++. Inside of C++ is a small language waiting just to get out; and for those of you who are serious C++ programmers, you know of its complexity and the issues that it faces.

So, one of the reasons why the Java phenomenon is taking off is that programmers actually like it. They find that it's simpler, and it has the support that you need.

Now, who needs a new language, right? So, we decided that we would focus on the business opportunities in the Internet. And our idea was to work with partners.

I have an opportunity to announce some new partners today as well. We've already spoken about Netscape as a partner that Sun had for a while. (Can you come on up?)

Our strategy is to license the technology first. If you want to use the technology in binary form, you may use it without any restrictions from us, whether it's noncommercial or commercial. We have been working with partners to take the implementation that we have done, the licensing.

In addition to that, the interfaces to the language, the specification, are all in the public domain; so if you don't like our implementation, with the open-interfaces and open-systems principles that we believe so strongly in, you may do your own implementation.

I'm pleased to introduce Marc Benioff, who is the senior vice-president from Oracle, to make some comments from Oracle about all of this. Go ahead. Do you have a mike?

Marc Benioff: Thank you.

Welcome; and through these various obstacles this morning, between the light and the sounds, the good news is that it's not raining. Torrential rains were scheduled for today; but I guess by various rolls of the dice we ended up with a beautiful day, which is something that we all can be thankful for.

Tonight, as some of you may know, at 5:30, Larry Ellison, who is now en route here, will be making a rare public appearance to announce the Oracle Web system, which will be the first public demonstration of Oracle's new Internet technology. We'll be showing some new browser technology, some new server technology, and a complete application development toolset for Web-based applications based on the Oracle data base, and also on Sun's new HotJava technology.

Oracle Corporation has been a leader in the development of open systems now for almost 20 years; and one of our most strategic partners during that effort has been Sun Microsystems.

Together, we've really been pioneering the concept of UNIX open systems, client-server-computer, and really bringing a new way of computing to the large organizations.

Well, we want to do the same thing with network computing. As Eric has been pointing out this morning, we're absolutely convinced that we're on the verge of a new paradigm. The first paradigm was the mainframe, the second paradigm was the personal computer; and now we're moving into the third paradigm of computing, the network.

As the networks becomes the next paradigm of computing, we need a whole new generation of software and services to make that happen.

Well, Sun and Oracle understand that very well, and we're working together very hard to bring that technology to you. So tonight at 5:30, we will be demonstrating that technology for the first time.

We'll be doing something else. Everyone who comes to that event will receive this CD-ROM; and on this CD-ROM is a full production Web server from Oracle, which includes our Oracle 7 data base as well as our new CGI interface and http server, as well as a beta version of our Oracle Power Browser, which is an application development tool for the Internet based on the visual basic language, and even has its own local http server right inside the browser.

We think this Power Browser, combined with the Oracle Web server, provides a new client-server solution for all Internet applications.

We'll tell you all about it, and give you a complete demonstration, at 5:30 today. If you come, you'll not only see Larry, but more importantly, actually leave with the software to make it happen.

Eric, see you later. Thanks, and congratulations.

Eric Schmidt: I'm obviously excited in helping Oracle make a strong endorsement of Java and the Java approach, and the kind of things I'm describing.

In two hours, in San Francisco, Macromedia will be announcing a major endorsement of Java as well. They will be announcing full endorsement for Director and AuthorWare, which are, as you know, their branded products. They control together about 80 percent of the market for multimedia authoring. They touch more than 300,000 creative professionals.

They're also going to be working with us on some multimedia class libraries in Java, and we will jointly develop a new tool for technologies targeted at high-bandwidth rich-media applications over broadband networks. Again, we're adding more folks to the Java phenomenon.

Now, I wanted to take a minute and talk about security, because I think that's important. It's the obvious concern. We take this very seriously. My view is that what the jet engine is to biological viruses, the Net is to computer viruses.

We believe that it is very difficult, because of the way Java was designed, using the browser technology that we have made available to our licensees, to write viruses. Part of that is because, when they run in that protected address space, we make sure that they can't do terrible things like delete all of your files. We will, over the next year, be adding significant RSA and other kinds of services and capabilities in order to make sure that all of that actually takes care of itself.

Now, the real question, and you all can spend a lot of time, go to Java, what are the implications of this new paradigm? I think the first is the impact on the business model in the industry. As I discussed earlier, this is the complete business model, the setup around an API lock-in. Well now, all of a sudden it's less important which platform you use, and more important which application you use. That means the power moves to the applications developer, which I think is a good thing.

The second impact is that it creates an opportunity for a new kind of computer device. There are a lot of names floating around for them. One was called the Net Surfer. It's a device that you hold that has http and e-mail access.

I've called it an impersonal computing device. It's not a personal computer, it's an impersonal computer. Think of it more as an Internet appliance. The idea here is that you would go up to some kind of a device, whether it be a nomadic device or a tabletop device, and with that device you would have access to the things on the Net.

So the trick here is that you can just walk up to these devices and get access to all of this information, and that may in fact fulfill the image originally that you've heard about PDA's and other kinds of devices like that.

When I think about the television, for example, the television is really an impersonal device. When you walk up to a television, you configure it. If you have children, you know they configure it to a different state than you left it in.

A consequence of this is that it turns all of our operating systems, really, into legacy systems; and it becomes much more important that the applications be HTML- and http-enabled.

This new Internet desktop that I was describing could be called a "net-top." It's something that has the ability to see the information, display itself, and so on and so forth. It's the natural successor to an X Terminal.

What's interesting with this new model, remember, mainframes had this benefit that you had centralized control, administration, things were backed up, but you didn't have any flexibility over computation.

PC's have this wonderful property that they're yours, and you can control who uses it and the performance and all that kind of stuff, but it lacks all sorts of systems-administration capabilities.

So in this new model, what happens is that both the program storage and the data storage occur on the server, which is [a] replacement for the mainframe, and that's the right answer. And the computation, that is the actual execution, occurs on the personal computer, impersonal computer, nomadic device, or what have you. That's the right answer. That's splitting the computation, the data, and so forth, exactly right.

There's another reason to believe that this will occur. Corporations have been studying the costs of this personal revolution, the costs of workstations and PC's; and most estimates have costs of administration and maintenance of those individual computers as many factors higher than the costs of the devices themselves, by the time you bundle in software and training and systems administration.

So any technology which allows corporations to more highly align and more highly centralize their servers, for example having servers where they store the programs and that kind of stuff, so they don't have to go out and touch all the personal computers that are in the corporation, is a huge cost savings. They can justify complete redeployment on that alone.

I don't know what the new business models in this world will be.

So here's some new software, where the software comes with the content; call it executable content. The data and the program come together, they run on any platform, they come over the Net, they can be cached if you have latency problems on the Net.

How do you sell those products? Do you buy them? Do you lease them?

There are some people who believe that the software model that we have today will be replaced by a complete inversion, literally a completely new model, where you will subscribe to components with a monthly fee.

Instead of buying what we historically view as monolithic apps, which take 10 or 20 megabytes of disk space and are as complex as operating systems, instead you will purchase on a subscription basis only the tools and components that you need.

And of course, as new versions occur, you will naturally get the new versions, because they get downloaded automatically.

That new model is certainly intriguing, and may in fact be the way the money begins to flow into the model that you guys and we are all proposing.

So, in the old model, you have monolithic applications with dead content. In the new, you have hyper-linked content with small applications.

I think that this is, by the way, a snowball effect. How can you-all help? Well, if you give us an implementation of one of your new data standards, we can include it in our technology and make it generally available.

We'd like to encourage you to think about using Java for programming. There are some estimates that one half of C++ is bugs or storage bugs, which are fixed in Java. Another half are exception-related, also fixed in Java. Another half of them are scripting-related, which are fixed in Java. So in theory your program should be significantly more reliable because of some of the changes that we've done.

And obviously we would like you to license Java from us and embed it in your new platform.

Russ?

This is Russ. Come on up. Let's see if we can do a quick demo. Russ has been wandering the Net, and let's see what you have found.

[Russ]: What we have here is, we're going to bring out a couple of things.

M: Can't hear!

[Russ]: What I have here is the financial portfolio demonstration, which shows the Java applet running here, when it comes up.

Here we go; yes. It shows the stock ticker on-line.

Eric Schmidt: For those of you who can see, don't be too worried about the stock prices. They're canned. It's not necessary to leave the tent.

And the idea here is that each of these graphs is an applet; and what they do is, as the stock ticker comes in, the graph shows the changes in the stock price, and then a little bit lower we actually have a spreadsheet object, which takes those and computes your net worth.

[Russ]: We have a couple other ones.

Eric Schmidt: This is one of the home pages off of Java, so you can run all of these yourself.

[Russ]: This is a nice little demonstration here.

Eric Schmidt: Again, each of these are applets.

[Russ]: What else we have here is, we show the same financial page on the Netscape browser.

Eric Schmidt: This is Netscape Java. Again, the important thing is, different browser, same input. We have the sequence right. It's the plane and then the car. (Laughter)

[Russ]: This is one I like. It's a crossword puzzle that was done. Here you can basically type in a word. It lets you know what's going on.

Eric Schmidt: Film actor? (I was doing the crossword puzzle.)

[Russ]: It's going to be...

Eric Schmidt: Cagney? . . . Keep going. This is a losing proposition.

[Russ]: Go back to a HotJava application. This app would actually stop loading. This is a derivative calculator that was written by a local systems engineer, coming up.

Eric Schmidt: We're waiting.

[Russ]: Yes.

Eric Schmidt: Something happened here.

[Russ]: This here is a nice one.

Eric Schmidt: Yes. Very popular.

This is the proof, of course, that a real demo is the test.

[Russ]: This is...

Eric Schmidt: There are many of these. Java appears to be perfectly positioned for making your pages more dynamic, more interactive.

We believe that Java will be a much broader language; but not necessarily for, keep going, not necessarily for a while.

We think the first users will take applets and will actually use it to spice up their home pages from a marketing and merchandising perspective.

[Russ]: This is StockPulse.

Eric Schmidt: This is the NanoTimes. This is a new newspaper, where you both get the data and, in this particular case it's a North Carolina newspaper. You see the ticker tape, and if you click to various icons you can choose programs and show them dynamically.

So, with that fairly brief set of images, what I'd like to encourage you to do is that when you get a chance, there are a number of machines that are Java-enabled around the show, you can play some more demos and get an individual idea of it.

I appreciate with all of you bearing with us in our tent, and thank you very much!
(Applause)

Bill Washburn: Ladies and gentlemen, thank you very much; and whichever of you had the car alarm, better luck next time. Sorry about the noise.

KEYNOTES ENTERTAINMENT ON THE INTERNET

INTRODUCTION

Jeffrey Dearth

President and COO, Magazine and Web Group, Mecklermedia

SPEAKER

Martin Schoffstall

Senior Vice President and Chief Technical Officer, PSINet, Inc.

Jeffrey Dearth: Good morning, everyone, and happy Halloween. We have a real treat in store for you this morning; one of the true early pioneers in the Internet industry, Marty Schoffstall, is joining us. He is the Senior Vice President and Chief Technical Officer of PSINet, Inc., which he co-founded in 1989. Just to give you a little bit of his background: Marty is a graduate of Rensselaer University, and he worked for BBN for a little while before getting the entrepreneurial bug and getting involved in various startup companies, including NYSEnet, which is the New York State Educational Network.

Many of you know that his company, PSINet, went public in May of this year, and since then his company has been very active, recently buying Intercon. He is truly one of the pioneers of the Internet, and he is here to talk to us today about real-time Internets and interactivity. Please join me in welcoming Martin Schoffstall.

Martin Schoffstall: I think the pioneer metaphor fits well in a tent; I just hope we next year can go to log cabins. I'm here to talk about some more pioneer visions with regard to the Internet. My pioneering vision for PSINet and the Internet is to look at the next generation of the Internet — which basically I call the “real-time Internet,” for lack of a [better] phrase — for both business and entertainment.

What the current Internet provides, from my perspective, in all its myriad forms, in myriad countries, through myriad providers, is basically universal IP for dial-up PCs to T-3 connected server platforms. This is an enormously complex worldwide topology and interconnection. It is basically ill-definable, because it changes on a minute-by-minute basis based on the next company coming in, [such as] the newest ISP in Ethiopia or a new trunk from some telecom company in some state, city, parish, or country.

The current Internet platform really supports an old application model, an application model that I got involved in in 1981. There are obviously lots of people who have been involved in the Internet application model or the Internet protocols even prior to 1981, but from my perspective the application model fundamentally is the same over the last fifteen years. To me, it looks like client/server; the Internet did client/server before we even knew what client/server meant. It does unicast, [where] one thing talks to another. Almost all the applications that we know today — clearly all the applications that the average engineer, programmer, CEO, or executive uses — are clearly in this old model.

The current Internet provides the model application/service paradigm that deals with textual applications and limited graphical applications — and, yes, I'm talking about the WorldWide Web. From my perspective that is a limited graphical environment at best; the current Internets do not provide anything like the bandwidth commitment, or any latency guarantees — which means delay guarantees — or any kind of prioritization, or any uniform, widely-used, agreed-by-the-community, agreed-by-business, agreed-by-all-the-application-people security structure.

As I think about the current Internet — again, something that I have been involved in for fifteen years, and have tried to move step by step through for all that period of time along with a myriad of other people, either in cooperation or in competition — I think the Internet really looks like the U.S. Postal Service in terms of metaphor; specifically, the bread and butter first-class mail. Believe it or not, the U.S. Postal Service is one of the most cost-effective mail movers in the world, and in fact it's number one according to most people's analysis at this point in time. It works extremely well when it works; and when it doesn't, like at Christmas time in D.C. or Mother's Day in Detroit, people get, at a minimum, frustrated. Now, if we think about where we were in 1960, this is all we had, pretty much — the U.S. Postal Service — to do what we wanted to do in terms of communications.

What I think is needed today is an additional Internet model. It's not a replacement model; clearly in the post-FedEx, post-UPS world the U.S. Postal Service continues to survive and grow. But we need an additional paradigm. From my perspective this can be driven by real-time Internet, which needs to support rich media that includes audio, video, 3-D graphics, and much, much more. That's not to say that the old model doesn't do this; it does, kind of, just like you can send any kind of multimillion-dollar scientific instrument through the U.S. Postal Service, or you can send your bearer bond of one million Deutsche Telecom stock through the U.S. Postal Service if you want. It's not that I can't do it; the question is, are those things the optimal thing to do in the old paradigm?

This new, real-time Internet needs to support newer corporate applications, which are things like real-time document conferencing, document management, et cetera... There are plenty of other applications there. We need to support gaming, which I am going to get into a little bit more.

And from my perspective, we have now built PSINet to do all these, to do the next-generation, real-time Internet. If I think of the new model as a metaphor, an additional model and metaphor for the Internet, I like to think about the FedEx metaphor. Minimally, what FedEx does is guarantee delivery; it prioritizes delivery and it delivers by a certain time. I say the real-time Internet basically provides the interactivity future that we have heard about probably for the last five years — and probably too much [about] in the last two to three. The real-time Internet is going to be the platform for the business end-user applications. I think of this real-time Internet as providing the bandwidth which will support the rich media types that we need for corporate and consumer applications. I think it will provide the low-latency, which will be obviously required for interactive media, real-time interactive media. Obviously, TCP/IP has proven that it is a universal programming platform, and obviously the Internet is the leverageable distribution media or mechanism that people ought to take advantage of. I think for some of you out there, this is not new news.

In the real-time Internet, I say that on-line doesn't work. We know all about on-line, or some of us do; centralized resources and proprietary architectures basically will not scale. The terminal-to-mainframe architecture won't work, centralized communications won't work, proprietary protocols won't work; they represent, from my perspective, high-latency networks, whether they're X.25 or router-only networks. I'm going to get back to that.

It's not going to happen because they're poor for any interactive applications. You punch your letter into the U.S. Postal Service — [the letter] that has a clipping of your engagement announcement — and you know it has the same priority as that million-share Deutsche Telecom bearer bond. Same priority, even though maybe one is more valuable than the other.

If you take a look at what on-line has done in terms of caching, from my perspective caching will not work in this interactive world. It somewhat works in the current Web; it has worked because what we had is thousands and tens of thousands and tons of thousands of people basically all trying to read or look at a shared document, a shared HTML piece of data.

That's not the interactive world, the interactivity world; these are once-only transactions, transactions with my friends, transactions with my business partners, transactions with whoever, and they are not in any way shared. In fact, they have a lifetime or a life expectancy of seconds, not hours, days or weeks.

My view of the required Internet infrastructure is very simple. We have the applications which we all use and we're all familiar with today; they are, of course, a shadow of what we will use two years from now, let alone ten years from now. We have the IP which we all know and love — or use because we have to, depending on your view — and below that we have to basically put in place in the Internet an ATM/FR infrastructure. We layer the IP routers over the ATM/FR switches in the worldwide Internet, we configure the specific servers and routers to take advantage of this ATM/FR infrastructure — which provides prioritization, the guarantees, and latency — and it works in the current installed base of applications and application models.

What this means is that we don't have to go back to every Windows 95 PC, or every Mac running Intercon software, or every PC running FTP software and upgrade it to some new TCP/IP that will only work for us. We can use the current installed base of millions of PCs, millions of servers and workstations, without change.

What we have is a situation of Virtual Internets. The PSINet technology that we have put in place, and is operating today, allows for Virtual Internets to be created within the PSINet switching fabric, the switching fabric at the ATM/FR switches. Not only applications can be managed and prioritized, but so can the Virtual Internets, for vertical applications or horizontal. Advances in network management and delivery of any virtual Internet benefits all the virtual networks within PSINet; we're going to talk about an application, a specific example where I think that is true. And my perspective customers, whether they be corporate customers or consumer customers, can participate in any of these Virtual Internets.

So from a picture perspective we have something that looks like this: we build the ATM/FR infrastructure; it is as complex as we need it topologically, and as complex as we need it technically — on the order of 200 to 2,000 ATM/FR switches, which is large. These switches exclusively move the bits around the country or around the world. To move the bits, we're not interested in using a router; routers are slow. Why are routers slow? Because they have a lot of header things to do, because they have a lot of routing things to deal with, because they have a lot of stuff to do. They're good traffic cops, and in certain applications they work rather well, but in the wide area, networking Internet they do not necessarily become a switching fabric for the highway system; that is for ATM/FR switches.

From PSINet's perspective, we put this in place in the first quarter 1993. Not 1995, not as a plan for 1996, not as a deal announced this week, but as something we actually had operational in 1993 in the first quarter.

Again, to build a real-time Internet we then add the routers. They're great traffic cops. They're great "homologators" for people who like to concentrate certain types of traffic; specifically, dial-up traffic is a good example. And we add servers, servers for the specific applications, servers for the real-time Internet applications that we want to see work. Now we can provide different types of IP service and IP topologies to support them.

Inside the switching fabric we, at a minimum, have three kinds of virtual IP networks. One is standard-priority Internet services that we all know and love, the stuff that we've used, some of us, for fifteen years or more, or some of us for only two to three. The second kind of service that we can provide is a lower-priority Internet service, and its associated servers. Now, you're probably thinking, what would be a low priority? Well, the good news is that you, as a corporation or individual, can decide what's low priority; you have that choice. We are going to come back to at least one application which I think is a low priority, but I'm sure there will be a little heat on that issue. The third [service] that we see in this real-time Internet, using this

infrastructure that is being built, is a high-priority, real-time Internet service with all of its associated servers.

From my perspective the key — and especially the key to the high-prioritization services, the real-time service — is that the servers need to be inside the network, and they need to be distributed. I think that is also true or more easily true with the lower-priority services, but absolutely true for the high-priority services.

Let's take a look at a high-priority application for the business community, which I call "business video." In this example, using your classical T-I pipe and your customer router, I now have — for lack of a word — two permanent virtual circuits, which is a terminology; but they could be switched virtual circuits if you cared, where 340 kilobits of that T-I have preempted access on the pipe to do business video. So if you want to watch CNBC, if you want to watch CNN, if you want to watch Donahue at work, that's a priority too, and you can ensure that that traffic gets to you. You can leverage your Internet application from PSINet to do this. The rest of the pipe is on another PVC where the standard IP services happen, which could be FTPs, which could be mail, which could be Web. Now, for your company this [high priority] is video; it may be rocket science in the future. Maybe your high-priority application is your Web server, maybe it's your coming audio server, maybe it's your FTP server; but you as a corporate customer get to decide that.

So what's the low-priority service? Anybody have a guess? UseNets, my favorite low-priority service. Again, looking at the T-I application, looking at a corporate LAN environment, you create a 128K PVC to the UseNet servers and to PSINet and you say, "yes, I want the data, yes, I want it when I want it, yes, it'd better be there, PSINet better provide it," and it will. However, as the customer, when the Web stuff comes in, when the file transfers come in, when the mail comes in that people have to use to do the job they are assigned to do, I want that to be preempted. I want 1-1/2 megabits of that T-I pipe to be used for the application services that I want today. And this example, this lower-priority service, PSINet has actually been implementing with approximately 50% of its leased-line customers for over two years. They can make sure that their pipe is not swamped by this specific location.

Now, you as a customer may decide that your low-priority service is the Web — I rather doubt it at the moment, but you could — and PSINet can configure that for you. Again, [that's something] in operation on PSINet today.

Let's talk a bit about entertainment, because I think that on the consumer side and on the individual side this interactivity, this real-time Internet world, can be seen more clearly there. Obviously on the Internet right now there's tons of informal entertainment; there's MOOs and MUDs, there's Network Bridge, there's some uses of C-U-See-Me for entertainment, X-Trak, and there's a few LAN-based consumer games. Obviously there's surfing the Web, there's chat, and tons of informal entertainment, the entertainment that we all do in a different mode at home with our neighbors, with our friends, with our family, and for us.

I think the next phase for entertainment is going to be formal; it's going to be real-time, and people are going to spend real money on it. The slide shows and the home videos are great for entertainment, especially when you look at yourself ten years later — and in my case see how much thinner you were or how better-looking you were — all of these are true in my case! But think about what it is; however you still spend the money for the formal entertainment of going to the movies or renting a video, the same is going to be true on the Internet because it is going to be the home of the interactive or interactivity applications.

A clear, absolutely clear example of Internet entertainment is going to be gaming. Again, for some of you I don't think this is new news. Gaming on the Internet will be a 1996 formal reality, formal as in people making serious money with serious players, using games. It is going

to be driven by home PCs with modems. And conservatively, I think when we look at the numbers — which are a compilation of the citations on the bottom — in June, 1995 we had about 33 million PCs, and 10 million of them have Windows and modems. That's not to say that there aren't Macs, or that there aren't lots of other things; but I am just focusing on one piece of this pie.

In 1995 approximately one-third of all on-line users play games. If we take a look at 1998, which is not that far away, there are 57 million PCs — again, conservatively — in the homes in the U.S. There's going to be 32 million with Windows and modems; and again, in 1998, approximately 54% of them by that point in time having some form of Internet access.

So if we look at 1998, make some guesses about how much people use this, two hours per month is very, very conservative. Let's say they pay an average of \$2.00 per hour; the gaming industry, the network gaming industry, could generate \$600 million a year.

So what are the gaming parameters for the future? What is going to make me choose to do this as a kid, as a geek, as somebody who doesn't have much time, as whatever you are? One [reason] is that the gaming is going to have to be real-time and low-latency. It's going to have to be 3-D. It's going to have to be titles found in computer stores, not custom network titles as is the dominant form today. It's going to have to be multi-player; it's going to have to support some form of socialization. I think it's going to have to require real-time distribution of players' voices, and the person on the next continent that you're playing a game with should at least appear like he's in the house beside you, and in an audio sense like he's on the gaming deck beside you.

Now, I don't think this is necessarily anything new. If you consider what we let our kids do on the Internet today, where they have communications, and friends, and e-mail and whatever else with people on other continents, in other countries where their first language isn't the same as our kids', we are not too far from games with those other kids, games with our acquaintances, et cetera.

Where is this going to happen? It is going to obviously happen in the home; but I think it is going to happen at work as well — because who can stop the Internet? Who can stop the Web? Who can stop games? And I see a world where this is going to happen in the mall. The Bally's game, the game that's sitting there at your local mall, that stands alone and has got the joystick that you like that you put a quarter into, will soon be networked into this Internet gaming world.

Gaming [will be] the "killer app." I think in the last eighteen months *Spyglass*, *Mosaic* and *nauseam* have delivered a killer app called WorldWide Web browsers. Now there's going to be more killer apps, and I believe that one of them is going to be gaming. [This statement is from] the president of Odyssey: he says that entertainment is the 3,000-pound gorilla in America's living room. Information, the information that we currently do and browse with our Web browsers, is important to many but takes a back seat; and this reality comes through in all of their research.

Yes, I look for information. I subscribe to *The Washington Post*, *Time* magazine, *National Geographic*, whatever it is; but how many hours, how many days do I spend on pure entertainment applications, whether it be the TV, movies or whatever else, or Sega, Nintendo, et cetera?

PSINet is now tuned to do real-time, multimedia, multi-player, interactive gaming. Servers are now in place for gaming partners to use; guaranteed low-latency for gaming or any other application is a reality. And the technology for gaming is usable for other business purposes, obviously.

So in summary, superior Internet technology is needed to provide real-time Internets for business and entertainment purposes. Demand for Internet entertainment is on the rise, and

will materialize in a definable way in 1996 in the form of interactive, multi-player gaming. All Internet users benefit from the superior technology and experience provided by PSINet, and from our perspective PSINet is uniquely engineered and positioned to provide real-time Internet services today.

PSINet is announcing strategic partnerships today with M-Path Interactive and its network publishing platform for games, and has title partners which it has announced or will be announcing: a partnership with MicroProse, with its *Civilization* game; a strategic partnership with Borta, Inc., for its games and technology; and a partnership with Vocal Tech for its *InternetPhone* software for Windows.

And I think that's it. Thank you, ladies and gentlemen, for coming today.

KEYNOTES

CROSSING THE CHASM

SPEAKER

Paul Gudonis

Chief Executive Officer and President, BBN Planet

Paul Gudonis: Thank you, Bill. Good morning, everyone. I understand from Bill it's a much better environment today than Monday, even with the clouds and perhaps the drizzle. I did happen to meet with Eric Schmidt, who faced the conditions on Monday. He was quite gracious when I saw him yesterday. He said just practice your speech in 45-second bursts. If I sound a little choppy, it's because I have been rehearsing all night and trying to time it between the takeoffs of 757s.

I am going to talk about the problems of commerce on the Internet and talk [about] the chasm we have. I will credit Jeffrey Moore and his book on *Crossing the Chasm*. The chasm that we face as an industry is participants who fear going from primarily communication to electronic commerce.

To cover this topic this morning, we are going to start and review the Internet past and present, it's use as a communications medium and talk about how we cross the chasm in the future, and if we do, what happens then; and the Internet industry agenda that I would like us to consider and adopt as we go forward.

The first question I would like to bring up, will the Internet matter? Certainly there is a lot of hype, press coverage, where they say there are 30 to 40 million connected, a hundred plus million in a few years, and the important aspect, as you know, [is] any computer will be able to talk to any other computer, any person talking to that device, working with that device will be able to talk to any other device on a network anywhere in the world.

The significance to me is that this will become the data dial tone. It's what we take for granted in telephone service. I worked at Ameritech and at AT&T. We took something for granted, i.e., telecommunications. If you have an agreement on open standards, on a unique numbering scheme where any device in the world has a unique identifier, you can communicate.

Any person in the world can talk to any other person through this network. We take for granted I can dial a phone and in Germany it operates over the phone lines, and I am connected. As long as we can both speak English [and] German, we have communication. This is what the Internet promises for our computer systems and people that use them.

If you look at the past, present and future, and you look at the Internet, until recently it was primarily a network infrastructure: file transfer, networking, Gopher, run research, academic institutions, often the engineering group within corporations. Presently it's an electronic publishing media which has taken off at an astonishing pace, with the establishment of the development of the World Wide Web.

The ARPANET was developed by BBN back in '69. Here is a picture of the network that existed in 1971, connected primarily for research and communications applications. It was the following year, 1972, when BBN's Ray Thompson invented using the @ sign that [which] we are all accustomed to. Ray invented using that for e-mail. That's part of our daily lexicon in terms of using the Internet and now we look at Ray as the Samuel Morse of Internet. "Ray," we ask, "What was the first message?" "I forgot. I forgot." "Make something up."

Well, the infrastructure was developed by the National Science Foundation of the United States and then was expanded internationally. The regional networks, primarily out of research and academic institutions — NearNet, New England Network by BBN, MIT, Harvard, Boston University, Stanford being the core institution for the Bay Net area, Internet, a variety

of different networks opened up across the world to provide the user access to the Internet resources.

Today that picture has changed. We have national backbones, international links, Web sites, thousands of Web sites popping up all across the world enabling people anywhere to have access to rich multimedia on-line. Also all the major on-line services providers — AOL, CompuServe, Delphi, Prodigy — providing a gateway for their users into this rich electronic public media.

Businesses have realized the potential. They are now adopting the Internet and the Web to electronically publish product, information, brochures, catalogues, press releases and report price lists, order status, for example, but it's still primarily a publishing media. What I think is typical in the adoption of a new technology.

Let's take what we are doing in the past and port it to the new technology. Let's take what we are doing in publishing information in documents and let's bring it to the Internet, to the Web, and publish it on-line. It's the primary way we adopt a new technology. We did that with radio, television. Publishing revolves around the power of the Web.

In the Web site I can create a storefront. I can have it serve as gatekeeper for information databases, and I was very excited about that. You can also link by hyper-link to other Internet sites on the Web, and also you can start processing some transactions. It's a very rich new platform for publishing.

What I thought we would do is take the present day on some of the business sites on the Internet. For example, I have got to plan a winter ski vacation. Let's go look at Copper Mountain. You have an example of what the ski conditions, information about the various programs and packages that they offer. Perhaps your choice is a warmer spot, and Club Med enables you to take a look at their various resort properties: Stage One, publishing information about their resorts and packages, Stage Two is received, and these companies evolve to taking reservations, lodgings right on-line.

Sun Computer provides customer service. Likewise, Silicon Graphics publishes a variety of information and a lot of direct customer support. You can link yourself to your customer by providing on-line customer support. A recent customer, *The Boston Globe*, wanted to become the information source on-line for New England. "Take our existing content and enrich and enhance it and bring that on-line to thousand of users."

The key point is providing access to corporate databases. We hear companies say "I have started to publish information. The only problem is it's static. My business keeps evolving. My product changes. My inventory changes."

Now we hear companies saying, "I would like to provide access to order status, to transaction records and history, to product information that is constantly changing and bring that on-line." So we see companies taking an end-to-end approach, saying the Internet offers me a true global client/server network. If I have a customer anywhere in the world connected, by having a Web service — I have a firewall to protect my information system — but allow users to get access so that I can check on customer profiles, product inventory status. I hear that United Airlines is going to allow customers to have on-line access to check on reservation status. We are working with companies to basically enable them to put together this end-to-end approach, in taking their information out to their users globally.

Another one is Federal Express. You can download a piece of software via the Web to check the status of your package. You enter an order number, and it will go into the databases and in a period of time it will return with an order status. Wells Fargo uses the Web to provide customers with on-line banking information transaction history. You can go in through the site as an authorized user and get information about your bank accounts and financial transactions.

Another example, Dell Computer, a very successful direct mail seller of the PC. They do customer configuration. You specify hardware, the software. They customize the package for you and ship it to you. It may take a couple days to have that happen. You are anxious about the status of your order. In the past you had to call an 800 number and a customer service representative would tell you the status of your order. Now Dell has a Web site so that you can actually go in, in a self-service manner, and check on the status of your order. A spokesman for Dell said traffic jumped dramatically into the Web site for this purpose, and the economic analysis, the business case is very strong. If they have to provide the answer by a customer service rep, it costs them about \$2 per transaction: to answer that phone, to pay for the phone, the staff to be able to check on the status. It takes about \$2 per customer inquiry, but by doing it on the Internet their cost per customer inquiry is five cents.

So that's what companies are doing, and we are helping essentially define the community of interest. Each company is the hub of a whole set of players, of customers, of prospects, of dealers and distributors, of trading partners, PR firms, banks as well as law firms, and others, and we see the Internet as really the opportunity to link all of those entities within your community of interest and improve communications, tie yourself more closely together on a world-wide basis.

So businesses have discovered that they can develop closer relationships with their customers and build brand awareness. I think what Dell is doing is part of a whole self-service trend that has been going on in this country where we are pumping our own gas. Take a case like the banking industry. The ATM machine enables us to do self-service 24 hours a day, seven days a week. You don't have to wait for Saturday morning from 8:00 to 10:00 to go to the bank to get \$100 out of your checking account. You can do that any time, and it enables the customers world-wide to have access to your information that you want them to have any time in a self-service mode. That enables dramatic cost savings.

The Internet is also emerging as an electronic marketplace, a place where we come together to exchange money, goods, services, information, and the early adopters have used it for publishing catalogues, price lists and promotions, and even have started to take orders.

One of my favorite sites, Godiva Chocolates, they now have Holiday Magic. You can order a box of chocolates on-line, or L.L. Bean. We just worked with them to develop their new electronic on-line presence. Now you can tour L.L. Bean's product operation on-line. The Internet Shopping Network, it's been very successful in creating a presence to market a variety of goods and services, running a variety of daily specials. FTD on-line. It's diversifying to an on-line mall. Even Pizza Hut. You can pull up a menu, enter a selection. You do have to put in your name, street address and your phone number so they can call you back. Right now if you put in an order, they call back and say, "Mr. Gudonis, did you really order 25 pizzas?" That's one of those security/transaction integrity issues that we face before we go forward to true electronic commercialization. Pizza Hut calls you back. We just have to work around that problem. We have got to collectively solve it if we are going to use the Internet for secure commerce.

Let's look at what it's going to take to cross this chasm. Today we are using it mostly for communications, product information, advertising, news, articles, frequently asked questions, electronic publishing on-line, commercially defined financial transactions, buying and selling, having an electronic shopping agent, having an RFP on-line accepting proposals from vendors, doing order entry, contracts being issued as well as purchase orders, all on-line.

Now to cross this chasm we have got five major challenges in front of us. The first one is security. The second is speed, reliability, directory services, and then payment systems. We need to work together as an industry as well as companies that want to use the Internet for commerce to build this bridge. I would like to go through each one of these.

If you look at security. You want to take orders over the Internet. Our buyer is going through the Internet to get access to an on-line information database. The first job is authentication of the actual buyer. As it goes out across the global Internet, confidential, that the message is not viewed as it crosses the sets of 60,000 networks currently interconnected as the Internet. When it arrives, it arrives with integrity as it reaches the server.

We need authorization. You may have sets of only your salespeople, for example, to have access to it. You have a method for authorization only for those sets of users. To get into the rest of the system, you have to go through a firewall. Then there has to be a process for non-repudiation. If we are going to use the Internet for commercial purposes, order a thousand widgets, first I send you an electronic order. I am running my assembly line, and they don't arrive. I call you. "What happened?" "Well, I never got the order." We need a method for non-repudiation. I sent you an order, and I can confirm that in fact you did receive the order.

Finally, what we have to have in place, end-to-end audit trails so we can track from the start of the transaction through its fulfillment that it happened. Because the Internet is evolving, it's immature. All these need to be developed.

The Internet industry is developing security solutions. Over 100 organization have come together to identify issues like the security issues and develop pilots to try developing solutions. Firms led by the Bank of Boston, Chase Bank, Chemical Bank, Bank of America and the Financial Services Technology Consortium working on how we implement effective security in electronic check transfers.

Last month we demonstrated the first transmission of a check on a demo basis. How do we now make this part of the institutional structure of the financial services industry?

The next topic we need to address is speed. We need faster connections. Two major technologies and players we're working with [are] ISDN, so we have digital tone into the home at speeds of 56, 128 kilobyte. [And] the cable companies are excellently positioned with a broadband pipe into the home for video programming. They've become a natural ally of ours in being able to provide LAN-type services connected by cable infrastructures. We have been working on both ISDN and cable issues to be able to use the infrastructure in place for Internet access.

If I am going to use the Internet for commerce at home, it has to always be on. Back to Pizza Hut. Every couple of days in my home the younger natives chant "pizza man, pizza man, pizza man." While they are chanting, I go to the den, turn on my machine, boot it up, dial in to an on-line service, log in, go to a search, look for pizza, find a pizza place, put an order in, wait for a call back; or I can go pick up my telephone, dial a number, and order a pizza, and it's there in 20 minutes. We need the ability to have a network appliance, the PC, in the home, in the living room, in the den, in the kitchen, it's always on like our toaster, our microwave oven, our telephone is always on. There is always power there. Unless we have that, we will see a limitation to people's adoption of the Internet.

On the network and business side, firms like ourselves are investing in tremendous capacity additions through the Internet backbone. Internet BBN was just awarded a contract by the federal government to design the next multi-bit router. Then many of our business customers are purchasing at least T-1 speeds, one and a half megabyte connections to the Internet for their multimedia commerce services. Some are now going up to speeds as high as T-3. The end result is no busy signal. There's nothing more frustrating than that, because the pipe or server are not big enough.

Web site availability, higher throughput, mirrored sites at different parts of the Internet so traffic doesn't congest to one site, better system management, end-to-end audit trails, time stamping. These systems will mature.

Now we are working with AT&T on a new nationwide network infrastructure. Our network operation will utilize a high-speed nationwide backbone with over 500 local points of presence for companies to connect to the Internet. We are significantly expanding two hosting facilities in Cambridge as well as in Palo Alto. So we can provide customers with high bandwidth access, to be able to have access to mirrored site adapters so that they can enable their customers to get access to their information databases on-line.

Directory services. Today how do I do that? I have to either know the URL — it comes from UNIX. It's rather cumbersome for the typical user. We need to be able to do a point-click type of approach. We need voice input, so I can speak to my PC and find my Web site on my location anywhere on the Internet, for example, for American Airline. How do I pay? Credit cards, slips, cash, paper checks, an electronic wallet. We are working on part of it. How do we do electronic funds transfers over the Internet.

What this will lead to is really a multipurpose network in the future. Whichever industry you're in, you can use the Internet for a variety of functions: advertising, selling, customer service, just-in-time supply, distribution of any types of products that can be bits, e-mail, of course, and video-conferencing over the Internet, which we have demonstrated.

As the Internet then evolves — if you remember that map I showed you of the ARPANET, that thin line connecting a few of the lines, it becomes a multi-layered infrastructure. There is a network infrastructure. There are secure electronic commerce services. We see manufacturers, part suppliers, consumers all plugging into this rich network which enables commerce as well as the public communication services as well as e-mail.

The Internet offers a lot of ways once we solve some of these other security and transaction problems. It's standard-based, world-wide and, importantly, it's multipurpose. I won't need a separate network for video commerce. I don't need a separate Internet to connect my EDI systems to my suppliers. By hooking up to the Internet, I will be able to do all these functions of electronic commerce in one cost-effective network.

Well, so it depends where you are in the food chain. If you are a manufacturer or a services firm that has something to sell, if you are a distributor, an agent, we see an emerging battle between different levels of distribution channels where manufacturers are saying I want a direct link to my consumers with lower cost, global reach, and small firms on the Internet look as large as the big ones. Consumers, whether looking for businesses or government or household items, should find lower prices and more convenience by being able to shop from the business or at home and go directly to manufacturers. So if you are an agent, you could look at the Internet and say I am an endangered species.

Ordinarily, we will see the channel fight back and actually capitalize on this opportunity as well. We see travel agents, retailers saying "I have customer intimacy. I know my customers. I have been serving them for years. I want to create a long electronic structure and put my suppliers at the mercy of me." I kind of feel like an arms merchant working with the superpowers as they formulate their strategies for dealing with this emerging infrastructure.

Whatever your business — insurance, banking, retail, travel, manufacturing — you need to look at what does this mean to your business and to conduct an Internet impact analysis.

There is an upside to this. You can achieve more revenue having global reach, improve customer service, lower your costs, or there is potential loss of franchise, loss of market share if you ignore it to new competitors who will capitalize on this infrastructure. My point is you can't ignore it. I suggest that you do an impact analysis to see what does it mean for my industry.

In the media industry, for example, television relies on advertising revenues. That means somebody has to be watching TV. If everybody is surfing the Net, they aren't watching the TV. Industry must look to how can I complement my brand.

This is a clip from *The Tonight Show* with Jay Leno. There is a live clip every day from Jay Leno's monologue. Here is a network provider who capitalized on the Internet rather than potentially losing customers.

What's the impact on news channels? Another customer, Turner Broadcasting, puts on one of the most popular sites of the Internet, the CNN on-line site. What if anybody can broadcast the news world-wide. What is the value of your franchise?

Earlier this year there was a tragedy in Japan. There was an earthquake. Before the international news crews could get there — it took a couple of hours to fly there with the crews — students from the University of Kobe on the Internet started to publish information world-wide. It actually had digital photos on-line well before the major news agencies got there.

In addition, they opened up a service. If you were a Japanese family in the United States worried about your relatives, you could send an e-mail saying "Do you know something?" "We will go look for them." It becomes a truly interactive medium. In the news business look at what type of opportunity that has. There was a recent volcano in New Zealand. You can get a picture of the current status of the volcano.

I spoke to an executive at the National Association of Broadcasters recently. We talked about two models of the television industry. The old model that you had, which consisted of an expensive studio with expensive gear and expensive cameras. You had to have a TV set which became a primary infrastructure. The question is what happens if anybody with a cheap camera gets on the unregulated ubiquitous Internet? There's a PC in millions in the home. What does that mean for your industry if you're in the TV business?

Well, as we go forward, I would like to address together a set of topics around public policy as players in the industry. Currently in the United States we have telecommunication industry regulation proceedings. The Internet is not regulated. We have to have fair competition. What is a copyright is becoming a big issue. Also, a lot of our regulations around specific industries have grown up around geographic boundaries.

As an insurance company, I'm allowed to do business in Massachusetts. Now, with the Internet, I can distribute services throughout the United States, enroll customers globally. How do we harmonize so I can capitalize on this global infrastructure? A variety of companies developing the encryption techniques, to have global commerce, have to have truly global agreements on the ability to export key technologies.

We are going to face redefining personal privacy. When everything is digitized, when I set my alarm, my coffee, what I buy at the doughnut shop, how many miles, who I talk with, who I communicate with, what Web sites, what transactions I do, once it's all digitized, it's in somebody's database. The question is what's the role of privacy? What as a society do we want to establish as privacy standards within the United States?

For example, I did some work with the telecommunications industry in Germany. We had modified our billing system because in Germany you are not allowed to put on a bill the last three digits of a phone number. The last three numbers are 'X'ed out. What do we as an American society want for personal privacy? There is First Amendment rights, the right of free speech, and censorship, responsible use.

Yes, I can say anything I want world-wide. What responsibility do I have for accountability for what I say? And do we as an industry, parents, teachers, for example, to be able to give them some control over what our children have access to.

Then as an industry, our growth has been ruled by open standards, by collaboration where companies are coming together with commerce, financial services consortiums saying let's work together to adopt a standard so things may flower.

We have to continue this spirit of collaboration, make it easy for consumers, especially people who are technophobes. People are still afraid of using a PC. They are afraid of trying to

set the VCR. We must create trust in the infrastructure so that one feels comfortable as a chief information officer to put my information on-line, take orders, and trust as user to put in an order.

In any new technology revolution like we are seeing with the Internet, there are unintended consequences. We have to think ahead, what could possibly happen as we introduce and capitalize on this technology.

I happened to pull out some predictions from the past. I will read those for you. Housekeeping is such a simple matter when organized and done over the wires. A morning's tiresome shopping can be done in 10 minutes in the comfort of one's own home. There is so much more time for pleasure and recreation and things that are worthwhile. This is a telephone company's ad in Philadelphia in the year 1905. It's talking about the benefits of the new technology called voice transmission.

Those that are involved in the technology and implementing it have got to remember it's really a people thing. That the Internet will affect how we learn, how we work, how we play, entertain ourselves, how we shop going forward, and how we develop our relationships, how we form new relationships, how we link ourselves with our family, whether they are children off at school or grandparents around the globe. Keeping that in mind as we go forward introducing this wonder, Internet technology, to the world.

Thank you very much for giving me a few minutes of your time to talk about how I see a crossing of the chasm and making a world-wide infrastructure. Thank you.

INTERNATIONAL COMMERCE INTERNATIONAL ASPECTS OF INTERNETTING

SPEAKER

Czeslaw Grycz

President, The Wladyslaw Poniecki Charitable Foundation, Inc.

Czeslaw Grycz: Welcome to this session on the international aspects of Internetting.

My name is Chet Grycz and my colleague is Laura Fillmore. We are going to be the duo that gives you the “Chet and Laura Show” this morning. We’ll talk a little bit about both of our experiences on the Internet, in terms of international issues.

To give you a little bit of background, my take on this is going to be mainly from the nonprofit sector, with quite a bit of experience in Central and Eastern Europe, and some other Third World countries.

Laura is going to be talking — from her perspective — on a more commercial side of things. So, with that as an introduction... Laura will introduce herself some more as we get into that.

Let me tell you a little bit why I can stand up here and tell you anything at all. It’s mainly down at the bottom here, and it says, “burned fingers involved in enriching experiences.” Indeed, all these fingers here have been burned in a variety of experiences in international work: in Romania, in Hungary, the Czech Republic, Slovakia, Poland, Bulgaria — all of those regions. Also in Mexico and Latin America.

Those are the reasons why I can talk a little bit about international issues. I have however, also done some work at the University of California in terms of large-scale electronic publishing projects. Those are extremely important to people in the Third World, in terms of access of information. There’s a considerable overlap in the kinds of work that I was doing at the University of California and the kinds of things that I do under the auspices of the Poniecki Foundation, which is a nonprofit foundation working mainly in Third World countries. We deliver Internet services, lectures and workshops, and we help librarians get on the Internet and begin to understand what it’s like to work and live in a digital environment.

I’m going to cover some Internetting issues today, things that we have learned from our experiences. [They will] probably be of use to anybody going into an international venue or interested in working in either in the commercial aspects or in NGO or governmental work.

There are a number of things that I think we’ve learned that we can tell you about. I’d like to give you a case study about a project that we initiated under a U.S. aid grant. It resulted in a ecological library directory of considerable size and scope. I think the process of making this directory on the Internet, and mounting it on the Internet, is a useful paradigm for many of you. So I will give you a little bit of detail about that.

Then I want to draw some conclusions and make some recommendations. What I’ll try and do is put on my predicting hat and predict a few things, and then you can come back a couple of years from now and say, “well, Chet you were wrong about this, you were wrong about that, you were wrong about that.” It’s also nice for me to see where things are going and try and give you some idea whether there’s any profit in this business at all.

The components that we’re going to be talking about are... there’s a whole batch of practical issues in terms of the wiring of the global information infrastructure, and the issues having to do with the different bandwidth in different countries.

For example, in Romania we’re talking about a country that has an entire bandwidth trunk line, serving the entire country, of 56K. So if we’re talking about WorldWide Web

development in Romania, you'll see that it's probably not the right place to be doing that. You'll find that there's a very slow response.

On the other hand, one of the things that you'll also find in countries that are impoverished in terms of the capital resources that they have is that they are enriched in terms of their theoretical understanding, and in their creativity.

When we were giving a workshop for about 65 librarians in Ploiesti, Romania, the day that we arrived there the trunk line went down. There was no Internet access at all to Romania. While I was spending all night trying to figure out how to make overhead slides out of pieces of cellophane, the people were up in the central office calling all their friends, among whom was the local TV producer. They convinced the TV producer to aim his satellite in another direction and we beamed down to Vienna and suddenly we had virtually T-1 speeds coming into Romania across the satellite. Everybody was quite pleased with that. We had a very successful workshop. It shows you the creativity and the skill, in terms of understanding the theoretical issues, which are oftentimes far advanced to most of our own computer scientists. They have it sort of cushy because they've got all of the material around and all the available issues.

Extending the Internet is important. This is the world's largest communication effort. It's probably the largest building effort that human beings have ever undertaken; it's an extremely important issue. I don't have to tell you this — it's sort of like talking to the choir — but when you really understand the fact that we have the capability of synergistically working as a world community for the first time, you begin to understand what in the '60s was a very popular book written by a French priest, Teilhard de Chardin. He coined the phrase "neosphere." It always seems very emotionally satisfying to think of his concepts of raising human consciousness. In fact, as we start communicating with one another across international lines and across cultural lines we do, in fact, begin to experience synergies that are quite different than they are in local areas.

One of the things that we find in Internetting and in doing commerce — certainly in terms of technological investments by human beings — is that it's a two-edged sword. On the one hand you'll find me reinforcing a fact that the principle role of the Internet is actually to build community. When you understand that this whole infrastructure exists, [you'll know] it's not about wires and hardware: those things are changing all the time. There's optimization of different kinds of functions on various platforms. In fact, the TCP/IP protocol and the leveling out that commits us to be platform independent is a way that sort of buffers us from the hardware issues. Although they are important, they're not what the Internet is all about.

Similarly, when you take a look at the software, lots of capabilities are being made available because of software and programming advances. It's not software that this is all about, either; it's really all about communicating and people-to-people contact.

When you think of community building — you understand that you have a community of some 300,000 people, let us say. As a kind of threshold, you actually have enough diversity to be able to build systems that will help encourage community life. You have diversity; you have contributions; you have networks that allow communication — and suddenly you have something that can enhance that community's well-being.

On the other hand, if you have a community of 3,000 people, the Internet is a very useful excuse to get out of that community. There's a concern. I'm going to be pointing to the positive sides of almost everything that I see. I want you to realize that on every positive side there's probably a negative side just as well. **We think of the Internet as community building, [but] it also can be community destroying.**

Globalization can take over communities. There are some interesting concerns about that. Similarly, as we talk about the geopolitical issues, the boundaries of international borders are going to disappear and get fuzzy as we have more and more traffic going across the Internet and across electronic systems. That will tend to minimize nationalistic fervor; yet, on the other hand, in many parts of the world right now nationalism is the kind of identity issue that is an extremely important component of growth and evolution into free market society.

So there are lots of very interesting issues here. I think the important thing, of course, is that this is a bi-directional communication medium. All of these issues — whether they are the ones that we like or the ones that we don't like — are susceptible to a lot of conversation. Americans, in particular, are not used to that. We like to be dominant, we like to give the truth to people. In a network environment, we have to be much more willing to give and take.

It was interesting to me, and probably to many of you, the kind of flurry that came around the IPO that Netscape announced and went through about a month ago or so. What that told me is that access is really what it's all about, because Netscape is an access vehicle. What we're interested in is the excitement of getting resources from remote locations — a whole variety of software packages that are integrated into one. In fact, that wasn't the issue: what was at issue was our ability to get that information. You see this in international work all the time. There is certainly a barrier in going through the kinds of software/hardware issues, but all of these are secondary to the fact that we want to get at resources; we want to have a vehicle to talk about the resource, the information content, the pride that we have in our local communities and our local skills and capabilities.

If access is the first key to understanding the Internet, then listening is certainly a corollary to that. Again, it's not a particularly American trait. And as we think of international work we have to develop new skills in addition to the ones that we have in terms of running business and handling things in that way.

The geopolitical implications are serious ones. In parts of Central and Eastern Europe, for example, there's a considerable resistance to the idea of the Internet. There's a resistance to the implications of what it means to have a society well-connected to outsiders. These are remnants of a command-driven economy. It's also a kind of fear of influence from the outside, and it's compelling because of the way that it's brought forth to a citizenry; it overtakes the local needs of that community to work within itself.

I think that there are dynamics about geopolitical issues that we don't fully understand right now, and we just simply need to be sensitive to those. Those are extremely important and delicate issues. I can actually even bring that down to an example in the United States right now.

There are two Senate bills and a House bill having to do with lewd, obscene and indecent material on the Internet. Now, it's bad enough that we don't know how to define obscene. Now we're adding the words lewd and indecent in these bills, which are even more [ambiguous]. We appear to be thinking in Congress that if we establish local legislation we're going to solve a problem. That is, in fact, an issue for a global environment, which we're not going to be able to control.

What's interesting about that process is that it is taking place in the United States. It's a politically correct kind of thing to do. It's a politically safe thing to stand out in front of a constituency and say, "we're against pornography on the Net" and yet it's sort of a silly approach to the whole aspect.

It's a demonstration that even in the United States, you've got geopolitical issues that are going to be different from the technical issues. [These are] different from the community-

building issues and different from the communication issues. Those political issues will sometimes be at loggerheads with what's going on in the Internet. Increasingly, as you look at the Third World countries, you'll find that conflict going on, too. It's nice to know that it's not always in their ballpark, though; sometimes it occurs in our ballpark as well.

[Here's a] fitting example of consensus decision-making — again, I won't spend too much time on this because you know that the Internet is a wonderful experiment, one that has no governing body. It's a decision-making process that is consensus-making. The issues that come up go to the engineering task force; the protocols that develop come from a wide variety of feedback. There's problem-solving with a variety of experts. What all of this suggests to me, however, is that it is the involvement of people that provides commitment.

We're finding that in many areas in which we're entering and saying, "here, we need to develop the Internet," that the way that you do that is to actually empower individuals who have some authority, who have some vested interest. It's their involvement that generates that commitment and then carries the ball further.

Again, there's this tendency for all people to walk in and say, "Look, I've got the solutions for you, do it my way and everything will come out quite well." In fact, we're finding in the community-building aspect, the deployment aspect and the implementation aspect, that's not a very successful approach.

Far more successful is to find the people who are really vested in improving themselves or improving their stature in the community, or wanting to accomplish something through a communication media such as electronic information. These are people who want to provide access to information for a constituents' group, to be able to have peer interaction — let's say for legislators and various counties with other libraries of legislative and legal materials — somebody who has a vested interest in accomplishing something.

You empower that individual by making available the tools, tool sets and capabilities — showing them the way. Suddenly you have maximized your effort because you have a number of people working toward the same goal. There needs to be a preparedness for commerce in every marketplace that we're reaching. And that preparedness, in many countries, is colored by the sociopolitical issues that have been a part of that cultural background. It's also colored by the fact that there's not as deep a penetration of computing power in the general populace as there is in the United States.

Even here, I teach at the University of California at Berkeley but I can go off 100 miles or 45 minutes into the Valley and I can be in communities that are not at all wired. So there's a dichotomy there in [terms of] the franchised and disenfranchised.

I have a good example about that where my brother-in-law lives up in the Mojave Desert above Bakersfield. I just recently established an ISDN connection in my home office, so I've got speed back and forth. It's really a wonderful thing. He came down and he and his wife — who is an attorney from Yale — do home schooling. They were very impressed with this and said, "Well gosh, you know this is great, can we get it?" I said, "No problem. This is ISDN, Pac Bell — they've got it all over the place. All you do is go back to Bakersfield, go back to where you are, call the phone company and find out when they are going to have ISDN in your area." 2017! I was impressed that they even gave him a date. But 2017? There's that issue of market preparedness.

You have to understand that not everybody, in terms of the message that you're going to be making, is going to be able, first of all, to receive that message in any coherent fashion [whether] we're talking about Web presence, or even if we're talking about network presence in a lower level of character-based FTP, or links, or anything like that. There's also the awareness and the comfort level of dealing with technology as a consumer. That's not yet developed, even in the United States. It's certainly not developed in some of the other

countries. The local standards, copyright and censorship issues are very similar to the ones we're talking about here.

Implementing bureaucratic government also has to do with a couple of other related issues. They have to do with confidence in one's self and understanding who I am and where I am, what my business is about — and being able to give and take with other cultures. Again, it's a very important issue to find out how business is conducted in different countries.

There are lots of nuances to the governance of business in different countries, and certainly in the Central Eastern European area. Unless you have a good guide, you will find that your money is going into a sinkhole. There [are] as many different creative ways of taking your money away from you as you can possibly imagine. It's a natural evolution of supply and demand: dollars are in demand, hard currency is in demand, and if you walk in naively thinking that you're going to be able to conduct business on the same level playing field that you do anyplace in the Western world, you're going find that that's simply not true.

People will very happily take advantage of you, and they'll do that with a smile on their face. They'll do that with such skill that you won't even know that you've lost your money until you leave. Now, I'm painting a bad picture, but what I'm trying to show you is the fact that there are different cultural behavior patterns and different cultural rules about how one does business in countries that are struggling to evolve in a free-market economy. There is a much more aggressive tendency to use those to personal advantage rather than communal, joint effort advantage. You've got to be sensitive to that.

There's also an issue in terms of collaborative tool sense. Almost all the tools, as you know, that were developed on the Internet were based on the needs stretching back to the ARPANET — where we were actually looking for remote job control and collaborative work among scientists. So the tools that developed were in fact related to communication tools, one-on-one or one-on-many. They were also related to remote job control. There are not very many tools developed that actually allow full collaborative work. Lotus and Lotus Notes, for example, seems to be moving in that direction, but on the Internet. you're not going to find very many tools that allow a good deal of collaboration.

That's critical, because you'll find that although the network community is certainly an English-speaking community, you nevertheless need to understand that there are different levels of comprehension of English.

There was a great article in the *New Yorker*. Some of you may have read about a Czech automobile firm that had Japanese workers and managers involved in it. They decided that the lingua franca, which I sort of enjoy, was going to be English. So the lingua franca was going to be English, and the Japanese, with their broken English, were talking to the Czechs with their broken English. You can imagine that there was something lost in the translation.

So in terms of very many of the e-mail messages that I exchange, for example, in the countries in Central and Eastern Europe, I tend not to react to them right away. I want to listen to them reverberate in my mind a couple of times because there are times when I'll get a message and it will be really offensive. I mean, it will be either hard-nosed — or somehow they've missed the point.

As I read it a second and third time, I try to listen to the accent someone may be writing with. I suddenly realized that some of my impressions were [based on] a particular understanding of the English language, and certainly levels of the written language. When we're speaking back and forth, we've got all of these body language images that help us in terms of communication. When we're using only written ASCII text — plus maybe smilies now and again — we don't have the full richness of the palette by which we communicate. Those are issues as well.

Providing mechanisms for free speech is related to the fact that this is what the Internet is all about. It's also related to the fact that we want to have a market area that is prepared to deal with this. So, we have to have more people connected, and more people working. It turns out, as I mentioned earlier, that in many countries that's a forbidding and negative aspect of Internetting. They're not particularly anxious to encourage things.

As a matter of fact, we've found that you have to work through the governmental agencies which are just as — in our case — very bureaucratic. They smile and say, "yes, yes, yes" but in fact, nothing happens after you come back the second year and the third year. So you've got to go through that process so that people can understand what you're doing. You also have to go through institutions.

We've been doing a good deal of work with the technical universities in each of these countries — helping them communicate with one another, finding alternate paths to get to various Internet drop-off points — building the network itself. It's amazing how important that is; it's also amazing how one individual can make a big difference.

And in the case that I told you about, the city of Ploiesti, the fact that there was someone who had a vested interest in making sure that they didn't have egg on their face by having 65 librarians with no Internet connection — and being able to use local creativity to come up with a satellite connection to Vienna — that's great. The more capabilities in terms of access to the WorldWide Web and the global Internet, the global infrastructure, the more powerful the ability for that network to function under all kinds of duress and all kinds of restrictions.

When you're working in Third World countries, and when you work especially in the emerging democracies, part of the job is to create linkages wherever you can. [You need to] help people make those linkages. So, we do that through institutions. We also do that through non-governmental organizations. There are a number of environmental groups, for example, who have set up bulletin boards and who have set up lists of one kind or another. We try to channel whatever foundation, money and support we can to get those people to become Internet service providers. That's useful for society, it's useful for the culture of the Internet, and it's also a preparatory step to working in a commercial environment. Mentoring on the Internet is, in an international context, extremely important. And mentoring is an activity that we should really understand.

[There's also the issue of] building communities. One of the things that people always talk about is how many users are on the Internet. We've been using the number of 40 million; there was recently an article in the *Chicago Sun Times* that said it's only 30 million. That's because a million people have multiple e-mail accounts, and you discount this. So it's only 30 million.

Well, 30 million is an unbelievable number. One of the problems, in terms of businesses, is that businesses look at this 30 million and they say, "gosh, if we only got one percent of this, then we'd be in gravy." And, of course, there aren't any techniques — or any acceptable techniques — to reach those 30 million.

Even if you could, what we really need to understand is that it's probably a million groups of 30 people that are really united in these on-line communities. That's good enough, because one of the things that happens on the Internet is that you get niche groups going. As a matter of fact, the commonality of interest is part of the thing that's of great interest to a business or a commercial venture that wants to market something. It's the self-selection that makes it valuable.

We have to think in terms of the fact that it's not 30 million users, it's in fact a group of communities that we can actually participate in and involve ourselves with. The real need for collaborative tools is particularly evident when you try and do anything in terms of marketing.

You must understand that in terms of running a business and conducting business on the Internet, especially in international venues, it builds entirely new conditions under which we can do that business.

First, it can no longer be partly because of the communication, partly because of the evolution of business, partly because of the understanding of world economic flows and inter-relatedness. It can no longer be an exploitative kind of an effort. We can't take our electric toothbrushes and send them down to Latin America because we can't sell them in the United States. It has to be a win-win relationship.

There's plenty of opportunity for us to strike joint ventures and win-win situations with people if our mind-set is that we want to collaborate with a group, and come up with something that helps them at the same time that it helps us. Those are the businesses that seem most often to succeed.

It's a mind-set that we need to develop for ourselves. The basing of information on open systems is something, again, that we've learned on the Internet. It probably comes as no surprise to you, but it's obviously a very important ingredient in doing business. So as you start working in a system that in terms of advertising — you know the changes that the WorldWide Web will have in terms of advertising — we realize that advertising itself can't simply be titillating.

The example I use in my classes is the Jeep ad on top of this rock in the middle of Utah. What's this Jeep doing on top of this rock? How could it get there? There's no road; you've got this helicopter that drops it down there. What's that for, is there any information in that? Is there any content that is really worth anything except to grab out attention? Not much. That might get still some play on billboards and on print magazines, but in a WorldWide Web environment or an on-line environment that's no longer a satisfactory approach to advertising.

What you want to understand is that it's an information system. You've got to be able to back up whatever titillation you have, whatever attention-grabbing issue that you've got, with a fact sheet, with a data sheet, with user information, with various evaluations and so on. The business of advertising and the business of marketing has to be much more open and much more information-rich than it has been in a print environment. And that's an extremely important issue.

"Cruising the market" is always something that amuses me. When I talk to U.S. businesses and Western businesses, they're saying almost always that there's this tremendous untapped market out there. That's what we want to get to.

When I go to Central and Eastern Europe, their answer is, "Boy, if we could only tap into the U.S. market, all our goods will sell." I think there's a real challenge here to understand that, as well open ourselves to reaching outside markets. There's going to be incoming access to our markets as well, and probably that's going to be a bigger one. So if you really are going to want to make it big in business, go over to a Third World country and start a business there. Then you can tap into the U.S. market. We're generally thinking in the opposite direction, if we're thinking "if only we can tap into this emerging market that's out in these developing countries."

All right. I'd like to now turn over to the second part of my presentation. It has to do with a grant; the Poniecki Foundation was a subcontractor. It was a U.S. agency for International Development Grant administered by the University of Minnesota. What we wanted to do was work together with environmental libraries in Central and Eastern Europe. The task before us was to help those libraries support the system of providing information to all of the constituents and their communities that needed environmental information.

It was a very interesting challenge, because the libraries in Central and Eastern Europe were not able to collect information on environmental matters over the last 40 years, or if they

did collect that information it was not in their best interest to make it available to the public. They were supposed to act as repositories and were, in fact, supposed to hide some of this stuff.

There is a whole mind-set that we had to change. In addition to that, we had change the whole understanding of what the transition is to an electronic environment in which access, not collection, is the issue for librarians. So this is very similar to business and enterprise as well, where you're talking not so much in terms of inventory and product sales as you are in terms of service and enhancing community work.

What we decided to do was to get the people to work together on a directory that we compiled entirely across the Internet. And so we called together representatives from six Central Eastern European countries; they met in Warsaw, Poland and we gave them some Internet training there.

We asked them to go back to their home countries and start working on understanding how to develop some Gopher databases, and also how to define the structures of the fields of information that they were to be collecting. [Also we asked them to] begin finding out where the repositories of environmental information were and to meet with us again in Bratislava, Slovakia a year later.

A year later we gathered all those people again. We repeated the process, but this time we started them working across the Internet delivering data. It turned out to a database in Vienna. In the process of doing their work, they began to understand what it meant to be communicating electronically, what it meant to be able to deal remotely over long distances as if you were sitting right next to one another, and what it meant to collaborate across nationalist bounds.

I must admit that one of the things that discouraged me about this project at first was when we sat down with the Czechs and the Slovaks. They speak the same language, virtually, and they can understand one another, but they sat on opposite sides of the room. They wouldn't talk to one another.

We had all of these difficulties in terms of cultural preparedness. Again, the point was that we started with a simple and rather insignificant process. In some senses, who cares about this directory? But in other senses, it was a task that was complicated enough that people got invested in it. So suddenly you found librarians empowered by the ability that they could work together on building a common product.

Then they mounted that product so that lots of other librarians could see what they were doing and be able to participate in building the database. I think that's a very good model. The idea is not to walk into a environment expecting total preparedness, not to come in saying, "here are all the ways in which you have to understand things," but come in with some empowering tools. [Then you] allow the human adaptive process to take the time it needs in order to get used to a new environment. And the electronic environment is a new one.

What was interesting in this "learning while doing process," building the eco directory, was two things. This was an U.S. aid grant. We also cooperated with the Mellon Foundation. It turned out that none of us had developed any kind of an exit plan.

One of the things that happens as you bring the Internet to new communities is that you raise expectations. Suddenly there was a raised expectation that there are going to be lots of things, lots of support and lots of on-going systems that are going to be provided to people. In fact, we didn't have the resources to do that.

And so, late in the five year program, we ended up by saying, "Well, one of the things we need to do is establish a sustainable body." This could very easily be a commercial Chamber of Commerce, or it could be a group of businesses in a particular industry. In our particular case, it's the International Organization of Information Specialists, the IOIS.

The idea there is to pull together some of the technical people at the technical universities, libraries, newspapers and Ministries of Information and bring them together. Suddenly you find that simply doing that is a big thing. As a catalyst who has the ability and the convenience of dealing with electronic information all the time — on my desktop, wherever I travel and wherever I speak — I take that for granted.

Then suddenly, when I go into another country and I bring together partners who I think are natural partners, it turns out that they've never spoken to one another. Those are totally separated and isolated instances.

The catalytic importance of this, and of doing business, is very important. But the business of establishing something sustainable that can outlast your particular investment is also important. When you do that there are a lot of surprises that come up. One of the things that came up was the realization, within the region that I've just been talking about, of a need to develop a new school for digital information. I'll come back to that in a second. This is obviously something that we didn't think about and wouldn't have suggested; but because there is such a collaborative work effort there we ended up developing that.

The lessons from the library project are several. The infrastructure issues — we really have to take those seriously. Not everybody has full connectivity, not everybody has continual connectivity. We're talking about all kinds of legacy systems that are very old, rather than workstations. Just understanding those differences is important.

The preparedness and commitment of people is something that has to be nurtured. It's one of those things that's like emotions; I can be angry and you may say, "the reason you're angry is da- da- da." That doesn't immediately dissipate my anger. An emotional life has its own way of playing itself out. Certainly in preparing and developing systems, in terms of electronic information it's similar. It's a brand new thing to many international venues.

There are behavioral patterns that are also important. One of the things that we did is set up a number of discussion lists for these groups to talk with one another. It turns out that nobody, for the first year or so, used those lists. The only people posting information were from the U.S. and the U.K.

When we got together at meetings I would rant and rave, saying, "You're missing the idea here. These are really wonderful communication tools, why don't you go ahead and use them?" Still, nothing would happen. Then it was during break time. I'm having a beer with someone at dinner, and they're saying, "In the culture that we've got, there's a respect for authority, so there's no way that I'm going to come up and say, 'here's what I'd like,' because after all, you are the professor and we're the student."

I wouldn't have dreamed of that being a real issue in terms of social communication, because when I teach at Berkeley I get students yelling at me all the time. But there's a greater respect, a greater hierarchy of issues. There's also the point that people don't want to reveal what they're really thinking, because there's a certain amount of distrust there. It could be all kinds of cultural issues. They are not all negative, but they are ones that we have to pay attention to.

So in terms of opening up, if you're trying to find a sales force and you've got all the sales potential, all the people involved in the [inaudible], you may find that it's not going as quickly or in the same kind of tempo or the same kind of dynamic as might take place in a company here in the United States. You've got to be paying attention to that.

The other thing that's very important is content. It's really the value in almost all international venues. We're very much product-oriented in the United States; in fact, in many other parts of the world it's content of a different nature. It's not so much entertainment, but there is scientific information that needs to be brought back and forth. There are real serious economic issues that people want to explore and figure out how to deal with, and there's a

seriousness about academic pursuits that is a little bit different and a little new to some business people.

Let me skip that. Let me give you a piece about indicators of quality on the Internet. This relates to a change from a print-based environment to an electronic- based environment, and it reinforces some of the things that I said before.

If you are publisher, if you are a writer, if you are a lecturer, one of the things that gives you some feedback and gives you some pride is recognition by one's peers — or recognition by a grateful audience or by a market that's going to pay for your book or your product. This we understand in a print environment. It's very important.

In a network environment these things become a little less important. Then you take a look at the next level. The next level of acceptability is to have an objective body — a professional, like a publisher — to accept your manuscript and impose their imprint on you. That gives you another level of pride and it's even more valuable than peer-to-peer because it is objective. It goes through some objective scrutiny and evaluation.

The seal of approval by your own society of peers is also important. If I'm an engineer, it's very important to have the approval of the IEEE on things that I do, or the American Chemical Association and so on. Most of that has to do with the evaluation process, which is this blind peer review process. All of that takes place in the print environment. We understand that very well.

In an electronic environment, what is happening is that the respected authority, the mentor, is becoming an important role model and a role catalyst in these things. Now, it's more important for me, for example, to find out what my colleague is reading and what lists she or he is listening to, and how they participate in things, because the mentoring is possible in a way that it isn't possible in print.

I can't always have mentors locally. I may have a mentor at Carnegie Mellon University; I may have one at Ford; I may have one at General Motors; I may have one at Manna. With a network environment I can now participate as a sort of a student to a mentor. Again, in an electronic environment, when you were talking about international work, this is a role that we play. Whether or not we're aware of it, it tells us how well we play that role. In fact, we're always going to play a mentoring role; we just want to be able to respect the power of having that role.

I told you about the International Organization for Information Specialists. It's mainly working in Central and Eastern Europe. Those of you who would like to do something good for Central and Eastern Europe ought to join that association. You won't get very much out of it in terms of "bennies," like local newsletters or meetings, but you will be doing something for people in the developing countries. It gives you an easy way of being able to find out what those differences are, what those people are like and what the cultural differences are.

Here's a thing that surprised us. When we started working — oh, this is now five years ago — in Central and Eastern Europe, we were the first to come in with Internet training, the first to bring in concepts of digital information and access to remote data resources. After three or four years — suddenly out of that mix of people who are working with us now collaboratively, not just as students — there came an awareness that there was a whole cadre of professionals. Now, I'm focusing on the library institutions because that's where I've been doing a lot of work, but it's also true in business.

There's a whole cadre of business people who need to be trained at the same time they are managing their business in an economically troubled, changing environment. The idea of an International Library School arose in touring Poland. This is where Nicholas Copernicus was born. It's nice there. What they are trying to do is establish a bunch of Post Graduate degrees where professional librarians who are actually working in the field can come in for one or two

or three weeks at separate times during the year for lectures that might be delivered by distance education. Some might be delivered by video conference, some might be delivered by exchange of faculty. Then they would go back and deliver their papers via the Internet to profs and people who would mediate those and then be able to do some kind of an internship where those librarians could go out and actually see what's going on at the [Bogulean] or the [Vivotech] National, or at the Library of Congress or anyplace else.

[Tape change]

Czeslaw Grycz: This helps develop a Post Graduate, on-the-job training facility so that these people can, at the same time as they are managing their own businesses, learn a little bit about the new ways in which business is changing because of digital information. It's a very interesting model, and I just wanted to let you know about that. It's a model that I think is going to succeed. We're in the middle of talking about that, and developing the proposals and so on.

All right. Let me come to some conclusions. Why you should be involved? I think there are several reasons. The ethical one is right up there. There's a certain responsibility that we have. I've forgotten where the quotation comes from, but it says "to whom much is given, much will be demanded."

I think that's really something that we have neglected in the Internet society. We've neglected it in the Internet on-line community; in fact, we have a great deal of richness in terms of the skill sets we have developed and the kinds of abilities that we have. We need to share those. There are some social reasons also, because I think that the Internetting experience and international Internetting experiences are the surest way to evolve the human presence on the earth.

That sounds sort of lofty, but in fact it's true. If we want to develop a peaceful world environment it's going to be based on open communications and open understanding of different cultural values and different interests.

From the cultural point of view, it's absolutely true that world populations are differently gifted. As a matter of fact, if we're going to advance at all we not only have to recognize and incorporate those gifts, but we have to be accepting of all of them. [We need to] see what new mix comes from that. That's something that, again —especially after the OJ trial, for example — I think we could do an awful lot of good for ourselves in understanding this component of the Internet, especially in America. Of course, economic business opportunities abound in both directions.

So my predictions: I think that by 2020 the Internet will be recognized as the most effective tool for decimating democratic free market philosophies. It's something that Congress, most of the higher education and most business people don't yet understand. This is probably our biggest and most effective outreach for democratic consensus building, decision-making and free-market economies.

It's an extremely powerful tool that we have, and it's a powerful tool because it doesn't have this backward look cast one to many — but many to many, and the mix that comes from that. It's a very exciting, challenging and enriching kind of process. I also believe that pure capitalism will not be allowed to dominate. There's an awful lot of concern these days about commercialization on the Net. You certainly get this question on the campus all the time: what's going to happen when MCI takes over? What's going to happen when AT&T gets in there? What's going to happen when Viacom puts in?

All of those influences will be there. But if we stress the community-building aspects, we'll also demand that those are preserved, because those are as valuable as any commercial economic gain. I also think that well before 2020 businesses will have integrated Internetting

into their operational system so it will become just a single piece of the work and the strategic plan.

So my recommendation is to focus on service. Think of service more than products, because that will get you a little bit further. Learn, seek out and value cultural difference — because that will enrich you personally and will make you better business people. I also suggest that you join IOIS if you want to support Central and Eastern Europe. I definitely think that you ought to involve yourselves in this International Library School. That's an awareness that all of us can benefit from.

One of the neat things is that the world is trying to deal with electronic information, pricing structures, access issues and so on. Having the school in which we're all involved, anyplace on the globe, will involve each of us in exactly the same kinds of issues.

It's a great area. I encourage you to be very aggressive about getting involved in international Internetting. For a couple of minutes, I'll answer any questions that you may have. Yes?

W: [inaudible]

Czeslaw Grycz: I will be happy to. Any other questions? Then I'll turn the floor over to Laura. She'll give you a less lofty perspective on doing business. I think that will balance pretty well with what I've presented.

INTERNATIONAL COMMERCE PUBLISHING AND DOING BUSINESS ON-LINE IN A MULTICULTURAL WORLD

SPEAKER

Laura Fillmore

President, Online Bookstore, Inc.

Laura Fillmore: I would like to introduce my colleague [Lydia Zalefski] here, and she is probably one of the first living examples we have of successfully doing business on the Internet.

Lydia came to us from Romania about a year ago. She heard about On-line Bookstore on the Internet and read a lot of the papers that I had delivered and said, "Well, I want to go work at OBS." So, that's Lydia Zalefski driving the machine here.

We had a very interesting question right before starting up. Someone came up and asked me whether this is going to be more about publishing or about doing business on the Internet internationally; and one of the things that has become clear to me is that virtually anybody who is doing business on-line is, in fact, publishing their business. I mean, it's a recorded environment on the Internet, and so if you're doing business you are, in fact, publishing. I think that a lot of the examples — we will be using three books as examples of doing business on-line — but I hope that some of those examples will be useful in terms of thinking about doing your business in the international environment.

So the presentation today will include nine maxims for doing business in the global environment. I can jump back a couple of years to one more anecdote about the first time that we really did an international publishing project. It was two years ago, when we got the rights for a Stephen King story to put up on the Internet. We did that in German and in English, and it really represented for the first time that a major author or major publishing company was doing business on the Internet.

It also illustrated some of what the most salient aspects of doing business on the Internet are. It's a distributed environment, and when we begin to work on the Internet we are creating something that has never existed before. When we proposed putting links into Stephen King's short story the editors and the publishers said, "No. You're not allowed to do that because what you're doing is going to change his story." In fact, yes, that's very true, and what we are doing in terms of publishing on-line is, in fact, different than any other kind of business model that publishing has had before; because if we look at the first maxim, we're looking basically at [the fact that] doing business on-line is a process as opposed to a product-oriented business.

So if we click on "I," you'll see that in the past publishing has meant creating a book, a physical product, and using the Internet as a distribution channel for that product. When we begin to do business on-line the ideas and information contained within that product are then released freely onto the Internet, and the challenge becomes how to make those ideas and that information fully available but not available for free. So what we've been doing is pioneering the business models which will enable people to access the ideas and information contained in a particular book.

One of the important things about beginning to work in the international environment is that there is no blueprint; there is no one right answer or one way to do things. What we've been doing in all the books we've been producing is basically trying a different approach with each project, because what we are attempting to do is discover the maximum number of users coming in and using or experiencing the information in a book as opposed to reading it sequentially from beginning to end.

A lot of the publishers — we've been working with publishers for three years while publishing on the Internet — and they'll come and say, "Well, Laura, are we selling more hard copies of our books yet? Are we making money yet?" And I think the key, the key question, is really instead of "Are we able to retrofit our product-based business onto the Internet," the more important question is "What are we actually selling?" Is it the right question to say, "Are we selling more hard copies of books by virtue of the fact that they exist on the Internet?" Might it not be more interesting and more productive and commercially viable to ask, "What, in fact, are we selling on the Internet? How do we sell ideas and information when a book begins to breathe and it enables itself to be accessed by its users? How do we charge for that? What's for sale?"

When beginning to work on the Internet, I'd like to encourage everybody to basically leave your brochures and your billboards by the side of the road, because retrofitting old models of doing business in a product-based world onto the Internet doesn't necessarily work. The real challenge is how to make your company available to the new global audience, not necessarily putting up a big sign and saying, "Here we are. Where is everybody? Come and buy things from us."

Okay. We talked about freeing the ideas, and [how] information doesn't necessarily mean giving them away for free. One of the basic challenges of working and doing business on the Net is that it's an adaptive machine; you can have an idea today and try it, but you have to be alive to how that experiment is succeeding. You have to adapt your business model so that it's not a concrete thing that you just pursue. It's an interactive process between you, the business person, and the user who is accessing your company.

So we'll go onto the second point of doing business on the Internet, which is "activity mirrors architecture." One of the salient aspects of the Internet is that it's a distributed system, it's not a centralized system; so that because of the fact that it's not owned by anybody we have to change our model of doing business. We're changing essentially from the product-based to the process-based business, and we're changing from terrestrial to cyber models. This calls for a fundamental change in the economics of doing business, which means cooperating as opposed to simply selling preconceived products to the world market.

Do you want to click on that, Lydia? One of the examples I'd like to point to is Nelson Mandela's book *A Long Walk to Freedom*, which we put up on the Net for Time Warner about a year ago. We did that in English, and that was using what we call the "sponsorship" model, meaning that our client paid us to put the book up, and the idea was that we'd get many, many hits on this English language version of the book. The result is that people who wouldn't ordinarily see the book would then go into bookstores and buy it, or would buy it through the On-line Bookstore. The hits on the book — the number of people accessing those files — have been rising over the last year, and I would like to attribute that to the fact that it has basically been an "internationalization" of that book that's been going on.

In April we got their rights from the German publisher to put up a German section of Nelson Mandela's book *A Long Walk to Freedom*, and the hits continued to rise after doing that. When we put up the German version of the book we also made an arrangement with bookstores in Germany and in the United States to be able to fill the orders for the German version of the book; and as the hits increase on this site they're increasing internationally as well as nationally.

Then we started to notice that there were a lot of people from Brazil coming into the server, so we thought "Let's respond to this marketing information and get the Portuguese rights to Nelson Mandela's book, to respond to the users who are coming in to look at Mandela's work." So we went to the Portuguese publisher and got the Portuguese rights to the book, and we put that up for the Frankfurt Book Fair, and the hits on the Mandela files tripled.

So what that means is that we're expanding the market for — you know, in the past, in the product-based model, Time Warner would publish the English-based book but it would be distributed in United States of America, North America, the Philippines, wherever the rights for that distribution are; but as soon as we begin to put up other languages the use of that book really changes, and the market changes. Instead of just being of interest to the trade book audience or the general book audience of people who are reading biographies, it becomes of interest to foreign language classes, it becomes of interest to more people overseas who can access multiple languages and toggle between languages, and it does increase the print sales of the book.

So the "hybrid" model exists; what we're giving away for free on-line increases the sales of the book, the product that they're effectively selling.

So the activity there then does mirror the architecture of the Internet, which is distributed. We're cooperating with the German publisher, the Portuguese publisher and the American publisher. We're not creating a product in one place and distributing it to the world, but rather we're using the distributed model of doing business to increase business for all three publishers in all three countries.

Using this same model in terms of doing business reflecting the architecture of the Internet, there's a fairly radical statement that Steve Wolfe of NSF, the National Science Foundation, said. He said, "Every client [is] a server," which means that everybody who has a machine, everybody who is connected to the Internet can, in fact, begin to do business and can, in fact, begin to be a publisher. What the architecture of the Internet [does is] basically take out the middleman so that the author can become his own kind of publisher; and in successfully doing business on the Net one avails himself of that opportunity by incorporating people and companies with their independent servers as constituent parts of a global business. A lot of doing business internationally does involve creating business partnerships with servers sited in other countries.

[I'd like to discuss] how we've addressed the legal issues of doing this, in terms of bookselling. How do we go about actually selling the books, which fuels the marketing money, which enables us to put the books up on-line?

That's basically through that distributed model, by cooperating with bookstores around the world; so if we get an order for the Portuguese version of Mandela, instead of our company buying Portuguese language books from Portugal and re-selling them — I mean, that's not my business. Our business is doing the on-line version of the book. We cooperate with the bookstore who is already set up to sell Portuguese books; and when we get an order for the German book, we've gone to Germany and created a partnership with a bookstore there who will fulfill the German copies of the books, because — as you might imagine — the whole international arena is fraught with existing laws about pricing of books and distribution of books and taxes on books. So how we basically address that issue in order to do the international business is by cooperating with terrestrial-based businesses who are already doing this. So that's basically the local-use maxim that we see there.

One of the last issues is a world that we've kind of invented for addressing the issue of publishing, [and that is] "cogniright," the right to think freely on-line. We're in the publishing business, so we're keenly concerned with the whole issue of copyright; and, in fact, we do have a copyright notice on the bottom of all of the pages which we publish. But I'd like to introduce the idea to you, and perhaps we can re-visit it in the question and answer session at the end.

[This idea is] the new notion of cogniright, our right to think freely on-line. To whom do our on-line recorded thoughts belong? I assume that most of you are familiar with the WorldWide Web for doing business, and living on the Internet. If you look and see your

session paths at various servers, to whom do they belong? And what kind of right of privacy do we have to the way that we interact with other people's servers?

I think this cogniright issue is an important one that we think about quite a bit in terms of doing business internationally, because a lot of the business that we do is based upon the business decisions that we make, and is based upon people's thought paths, people's paths coming through our server. So the question of cogniright, I think, becomes more important the more business we do.

Let's go back to point number three. Finding your customer means enabling your customer to find you, "customer" being anybody who's out there on the Internet. And again, this goes back to that first maxim about how doing business or publishing on-line is a process as opposed to a product-based business. You can't just take your brochure and put it up there and say, "Well, I'm selling watches, and so here is everything you need to know about my watch," and wait for everybody to come in. You have to give as well as get information on the Internet.

In thinking in a new way you're going to want to figure out what you can give away for free in order to get the traffic into your site and be able to sell whatever it is you're selling. And again, to go back to the question, "What is it that's for sale?" I believe that once you start to do business on the Internet you'll find that some of the preconceived notions about what is for sale might become very different indeed. In fact, what you used to charge money for or what you are today charging money for in a terrestrial-based business might, in fact, be free, and what you haven't been charging money for might be charged for.

Let me give you an example. This is, again, a book publishing example. Right now if you go into a bookstore and you say, "Well, I'm a beginner astronomer and I want to find a beginning book about stars, and I want to spend \$20.00, and I need it by Friday," you would ask the clerk [those questions], and if the book clerk is an intelligent book clerk familiar with the business they would tell you what book that you want to buy. There's no charge for that information, and the bookstore makes its money by selling the hard copy of the book.

I think that as we do — and what we're finding is that we do more business on-line — that perhaps that book will not be free but that information, that intelligence from the book clerk, may very well be what's for sale. Okay? It's an idea. It's an intangible, and the challenge before us is to figure out the weighted value of that information.

Same thing with a hardware store. You go into a hardware store and, you know, your toilet is broken and you need some kind of joint to put on it. You don't want to go to — you don't necessarily need a product catalog in order to shop from; you need the intelligence of the person to say, "Oh, you've got this kind of joint, this kind of pipe. This is what you need." That intelligence may very well be what's for sale on the Internet.

And a third example from what we've been talking [about] is with advertising marketing firms. My company had a link that I started twelve, thirteen years ago. It used to be a product-based business where we would go and sell the capability to create brochures and books to publishers; we went into the advertising company, and what they wanted to buy from us were the ideas about how to advertise and market on the Internet. What we used to charge for — the whole production process of creating a booklet — we're doing that for free. What they're paying for is the idea, is the intangible. And I think that's a model for doing business on the Internet.

I mentioned the Mandela book having its market changed by doing business on the Net, and increased, in fact, by virtue of the fact that it is an international publication. If we consider that doing business and publishing on the Net is "contextualizing," as opposed to just putting content up there, it's the context that really matters; it's the capability to interweave what your product is or what your book is with the other available resources that are out there on the Internet.

As a business person or as a publisher, one seeks not to necessarily push or promote a particular product or book but rather to create an interest area, a generic interest area which many people will visit because you're giving away information. So if your business is, for example, a shoe store, instead of just putting up a product list of all the shoes that you offer you would really want to be seen as "shoes.com," so that people would come to you to learn all about walking and all about shoes. That's what's going to bring the traffic to your site, and traffic is the desideratum of doing business on the Net, because you're not going to be able to make money and determine what your business is unless you get that flow of tens, hundreds, hundreds of thousands of people coming into the server.

We'd like to go on to Item number four, [which is] "customized access is better." Access is all; customized access is better. When doing business on the Internet it's important to realize that everybody out there it is not only an English language-speaking audience. We've been lucky to be working with a best-selling author, [Bernice Chessler], author of *Bed and Breakfast in New England*. We've been her agent for many years, and we've been publishing her book on-line. She started out publishing "zoom" books for WGBH TV as an author, and she's published many books since then and has been working — [she's] actually the first author to put her book up on the Internet in distributed version with On-line Bookstore. And now this is the second edition of *Bed and Breakfast in New England*.

Where this is different is that it caters to the international market. Increasingly, a lot of bed-and-breakfasts in the United States are receiving traffic from overseas; so Bernice thought that in order to pioneer a new model of publishing on the Net she should cater to not only the on-line audience, but to the international on-line audience. In so doing she has created a distributed project which involves linking to many of the aspects out on the Internet.

So instead of having a linear book, where one begins on page one and proceeds through the end, one can access the book according to the custom uses that each reader has in mind. So, for example, if we think, "Well, we want to travel to Cape Cod this weekend, it looks like it will be a beautiful weekend," we're accessing the book not only through the table of contents and through the index but through the graphics in the book.

Another interesting and key point about this is that Bernice's book doesn't exist yet; Chronicle Books will be publishing this in January or February. So what this is doing is, in fact, increasing the market for the book before the book exists, so we're using the Net as an advertising vehicle. If one is a German citizen and wants to travel to United States, they're going to seek out the custom access to the book and seek out a German language [facility]; they want a host at a B&B who speaks German.

So what we can do on-line far exceeds what we can do in paper in terms of enabling the customization of the book, of the product. The book exists in English; we translate it into German to make it accessible to that audience. The book is one-color type throughout; we can include four-color pictures at much, much less cost than it would cost to have four-color pictures in the book. The book has those general maps or maps that look kind of like what you just saw on the screen; here we can offer customized access that will take you to the dirt road right in front of the house by linking into [Delorme Mapping Service]. And that illustrates another business model for doing business on the Net, where this book is now freely accessible to anybody who's on the Internet.

Where the opportunity for making more income for the author and for the publisher comes in is in the aspect of microbilling, in charging for those very customized accesses to the book. So if I want to find out, you know, exactly what the dirt road level is to the B&B I want to travel to this weekend, that could cost 25 cents or 50 cents; it's a microbilling model in addition to the freely available text up on the Net.

So let's say your German citizen — well, this guy wants \$119 to come to my B&B this weekend. How much is that in Deutsche marks? So by virtue of linking, linking with the book, you can go to Travel Links — at the bottom, Lydia — and then we can look at the currency converter. You can change the dollars into Deutsche marks, so that as well as customizing the maps you can also customize the currency converter. We can take a look at the Dbase chart, right? So you could customize access to the book.

We can move on to number five. Is it still live? Okay. "Link-think in multilingual mode." We are what we are by relation. Basically, the kind of work that we've been doing is what's called "distributed publishing," and what we do is enhance or expand the content of a particular publication by contextualizing it through linking. Another book that we've been working on is one for Random House, *The Practical Guide to Practically Everything*, and there we've been licensing links so that instead of actually buying information to link to this particular book we've been licensing information — which, again, enables the reader or user to customize the book to his or her own needs.

So if we take a look at the "Health" section of *The Practical Guide to Practically Everything*, you'll see the red triangles indicate chapters of the book, which are basically exactly as they exist in the publication. And, again, this one was done prior to publication, so it serves as a marketing as well as on-line publishing; it serves as marketing for the hard copy of the book. If we look at the Health section, you'll see the bottom line there without the triangle next to it is new contextualizing information that we, in fact, license from the people we're linking to.

So, for example, if you're reading about cholesterol in the Health section, this will take you to a specific page whose content we have licensed from Harvard Medical School. So we're not just illustrating what's in the book by virtue of linking to external sources, we're in fact licensing from the people at these organizations so that we're getting specific content linked directly to what the book is all about.

What this is really called — we're calling it a "living, breathing footnote." In a paper book, if you have a footnote that's at the bottom of a page, that's going to point you to another source somewhere on the Internet; whereas when you're publishing on-line you not only point to another source but you also include it — you actually include it with the publication so the reader then determines how far he goes into a specific content area.

Another example of internationalization in this regard — Lydia, if we go back to the "What's New In Health?" — is *Der Spiegel*, because they too have agreed to be linked to this particular book. So if you're a German reader, and you're interested in what the archives of *Der Spiegel* magazine, the German news magazine, have to do with current health issues and specifically cholesterol, this link into the German server will enable you to do that. So what we're doing is essentially, again, building contextual fields around particular content areas, which serve on the one hand to spur the print sales of the book by virtue of the many, many hits on the particular book, and then secondly serve to pioneer a new business model which we're calling microbilling. As the information gets more customized to each reader or user, then it becomes clear that the reader or user will be willing to pay small, incremental models, incremental amounts of money, for that information.

A third type of link that we've put in is the link of the human being. *The Practical Guide to Practically Everything* has many experts behind it who have contributed to the various aspects of the book, and so we created a forum; in fact, again, this is a licensing arrangement with books.com where we have our book situated in their Forum section so that the people behind the book are able to talk to the people in front of the book. So the experts who inform the ideas and information the authors write about can talk directly to the reader, so we have a kinetic on-going aspect to the site.

That same sort of interaction is possible in [Bernice Chessler's] *Bed and Breakfast in New England* where we have the postcards to the author, where the readers are able to write to the author of the book and, in fact, write to the individual B&Bs, so that the book becomes a process and it becomes alive in a way that a static, paper book finds impossible for that to happen.

Let's go on to number six, Lydia, to "Adaptive Machinery Speaks Many Languages." We're taking a look at number six in developing relationships and linking relationships with other businesses who are involved in the projects that we're doing. What we're sharing is the income model and the billing model; but we're also, importantly, sharing the information, because what people are most interested in at this point, again, is the attention and the use that people make of the particular server.

So with the Harvard Medical School or with *Der Spiegel* and with books.com, what everybody is interested in is how people are accessing the various servers, what the path is and what the session path is through the various sites. And we're paying attention to those statistics because that's indicating to us what is succeeding commercially and what is not succeeding commercially, so that we can adapt our structure and adapt our approach accordingly.

If we take a look at the "Global Book," this is an example of what we've pointed to thus far. *The Practical Guide to Practically Everything* and [Bernice Chessler's] *Bed and Breakfast in New England* are both real projects; these are real books that either exist or will exist soon. In order to develop good relationships with publishers and other companies overseas, we're pioneering books that don't exist yet.

In fact, I'd like to talk for a minute about EInet, which is an Internet service provider in Germany. Together with them and the Frankfurt Book Fair we've launched a new project called "The Global Book," which is a book that was started at Frankfurt Book Fair about three weeks ago and was initiated by the Frankfurt Book Fair and CDC, which is the advertising company behind the Frankfurt Book Fair. They've asked us to put together an organizer project over the next year, in multiple languages, which will end up being a book published by a publisher in this country and overseas. That type of cooperation takes us further than just marketing books — which already exist — into creating books and creating business models which can be adapted for other uses.

Where are you going, Lydia? Yeah. If we look at Deutsche we can see that. So this will show you the constituent parts of the collaborators in The Global Book project, which is basically, as I said, an advertising agency, an on-line service company in Germany. It's the Frankfurt Book Fair itself, it's the AAP, the American Association of Publishers, and it's a lot of different complimentary organizations which together are going to create a publication of a kind that hasn't been seen yet, because it is an on-line publication which will become a product-based publication.

Where it's initiated is on-line. We invited people to begin to contribute to the book and publishers are, in fact, supporting it in terms of contributing editorial skills.

Here we're back at books.com, and we see the beginnings of what will become The Global Book published at Frankfurt Book Fair in 1996. And it presents a lot of the issues about on-line publishing.

It starts as an English language book, and the contributions are coming in many, many different languages. The first one, obviously, is the German one because that came from the Frankfurt Book Fair. What we're looking at is the initial announcement from the Frankfurt Book Fair about The Global Book project. If we look at [Fredrika's] contribution we'll see a German language contribution to the book.

One of the challenges and one of the participants in The Global Book will be the Internet itself. Some of the tools and capabilities of the Net will be natural language translation

capabilities, so that we will be putting this German text through a natural language translator to create an English language text, and in so doing will define for the participating publishers and organizations what type of publishing business succeeds where the commercial models lie on the Net.

We should take a look back at the Mandela, Lydia, because that — I'd mentioned earlier we began that project with Time Warner — that illustrates the collaboration not only of book publishers here and in the United States, but it also illustrates the collaboration of multiple types of companies on one particular project.

Again, where this is helping the publishers, helping the companies we're working with in terms of books — just recently we've added a site at Miramax Films, and we're going to be working with them to do *Cry The Beloved Country*. *Cry The Beloved Country* has to do with [Alan Patton's] book and South Africa, and the link from Miramax into Nelson Mandela is going to increase, again, the number of people who are coming to the site to experience not only the book but also the film. So we can take a look at the Miramax site which will lead us into Nelson Mandela. We could just start up at the top, at miramax.com.

So the important thing is that multiple companies are here benefiting from on-line distributed publishing. This is a site — and I'm giving you kind of a preview — this just opened about an hour ago, and it wasn't up here yesterday. And so the "Miramax Cafe" is where we'll travel.

Miramax is, again, doing the film that has not yet been released, *Cry The Beloved Country*. Last week, at the premiere in New York, Nelson Mandela spoke. It's a book that was written back in the '40s. If we click on the "Concession," what you're seeing, again, is the licensing, is the interlinking of multiple sites.

If we take a look down at "Books," here's a book that's published by Simon & Shuster that's going to be — that is, in fact — included into the contextual web of books about South Africa. This is leading into the Internet version of Nelson Mandela's book, so that Miramax Films is able to capitalize on the tens of thousands of people who are coming into the site to experience Nelson Mandela's book; and, on the other hand, the Nelson Mandela publishers are able to capitalize on the many people who are coming into experience *Cry The Beloved Country*.

So what we're doing is what I mentioned a little bit earlier, the whole idea of creating a contextual site, a general type site, that is not just one book being marketed. It's not the graphic image file of one book and a sample chapter which is selling one copy of one book, but rather it's the evolution of the context of ideas in a particular subject area. So we can, in fact, sell you the book from the server, and that capability has become a lot more sophisticated recently. We can, through a secure Netscape server, take your credit card and sell you a copy of the book, which is what the publishers have been interested in all along in terms of doing their product-based business.

What's illustrated here is kind of what we're trying to do, and that's make a seamless jump, a seamless leap for the user so the user doesn't necessarily know what server he's on. We're linking together servers all across North America and Europe in order to do this; but right now this is a basic "buy" form. If you want to go in and buy a copy of *Cry The Beloved Country* or any of the Miramax-related items, here we are within the store. You can click on "Books," and so this kind of addresses the publisher's basic interest in selling physical copies of a book, and we're selling to the global audience.

You know, it's not just people who can walk in the physical front door of a bookstore, but anybody in the world who's coming to buy this book. And again, the fulfillment is not us buying from the Miramax stuff — which is coming from twenty, twenty-five different sources, and we're distributing that fulfillment out to people who are inter-networked with us. We're not necessarily buying and selling the physical things ourselves, but I think this capability of doing

business and taking money over the Net is an important component that people have been looking for for some time.

In the meantime, what we're finding is the important business for the film company and for the book company is the marketing and promotion which comes from the distributed version of the book. If we can go back to the distributed version of *Cry The Beloved Country*... We're in the store right now. We leave the store, and we can go to the Internet version of *Cry The Beloved Country*, which is in the middle, and that itself is an interweaving of the movie — it's *Cry The Beloved Country* the book, it's Nelson Mandela's book, it's an inter-linked project which is going to change on a daily basis just as a movie changes on a daily basis. At any time you the reader can go back and buy a copy of the book, and the more people we have accessing this site the more people are going to buy Simon & Shuster's book. They're going to buy Time Warner's book and they're going to go see the movie *Cry The Beloved Country*.

And another interest — there's the link, Lydia's pointing to *The Long Walk To Freedom*, and we click on that and that will take us back to the Mandela project. So it's up to the reader; it's a reader-driven medium, and the reader can determine what book he wants to go into more detail about.

Do you want to go back to the talking points? I think we should, because we're going to have to come to a close fairly soon. So this project, I think, illustrates quite nicely the whole idea of "contextualizing" not only many different businesses but also many different international businesses. Our job with the Mandela book is to basically interweave companies doing business in multiple languages and to sell products in Europe and Africa and around the world. I think that has effectively shown that.

Let's jump to number nine, Lydia, and then I think I'd like to open up for questions. The files for this presentation are available to anybody who wants to access them up on the Internet, and also through meckler.com. But I think that one of the most interesting things about what we're doing this morning is the fact that Chet [Grycz of the Wladyslaw Poniecki Foundation], who preceded me in giving his presentation, and I haven't really talked for six to eight months, and a lot of what I'm saying about the importance of the evolution of an economic model to enable people to do business on the distributed Internet fits really well on what he's talking about conceptually from an educational point of view.

We are, in fact, implementing this with companies around the world in multiple languages; and just looking out at the room I would assume that the people in this room have a collective connectivity capacity that far exceeds a lot of the countries and continents that we've been traveling on. And I think that therein there's a great responsibility for all of us to do good and important work in terms of developing the on-line thought machine, which will become the business model of the future in terms of our information-based society.

I would like to open things up for questions if anybody has any questions about publishing on-line or about doing business in an international environment. We've got fifteen minutes, and we've been doing this for a good number of years, and I hope that we'll be able to answer questions — either I or Chet, who's in the back there, or Lydia. Yes?

M: Could you talk about what your user interface is going to look like? Can you talk about your model of [inaudible] media transactions or whatever?

Laura Fillmore: Microbilling?

M: Yeah.

Laura Fillmore: Well, the store is probably the beginning step of that. We have been negotiating with a credit card clearing company which will enable us to do microbilling down to pennies, because I really think that that's important, the "penny for your thoughts" approach to things; so that people would come into the store, and if you click on, say, [Bernice Chessler's] book, *Bed And Breakfast In New England*, and you say, "I want this map, and I want it by tonight," you have specific information that this would cost 10 cents or 20 cents or whatever the micro amount would be. That would accrue until a plateau is reached of five dollars, and then the five dollars is charged to your credit card.

If you look at the store in the sign-in procedure, you are supplying your credit information and becoming a member so that when the microbilling model is implemented, then it's through that kind of vehicle. But it's also — to go back to the store — it's also something that the user would be very aware of, so that you're not going to be charged without knowing it and get credit card bills without having approved them in advance. You have to take your aggregated ideas and contents to the cash register before you can leave. Yes? In the back?

[Tape Change]

M: [inaudible]

Laura Fillmore: We've done both. We do sections of books. In *Bed And Breakfast in New England* the whole book is going to go on-line.

One of the most successful hybrid models is one we did with McGraw Hill, *The Paperless Publishing Book*, where we have the whole book there on-line. A lot of people say, "Well, how can you do that, because if you have the whole book on-line then who's going to buy a paper copy of the book?"

I would argue strongly against that because, as you've seen from some of the books that we've shown here, these are really chunked up so that if you went into *The Practical Guide to Practically Everything* and stripped out all the codes and printed out the whole thing, it's going to take you hours and cost you much more than buying a copy of the book. So that the argument with publishers is that putting the whole book up is a very positive thing. So, yeah, we do put whole books up. Yes?

M: I'm very curious about the state of development of machine translations. How far have we come? You know, what's the viability of that in a book fair?

Laura Fillmore: Hmm?

M: Or a project in terms of getting the liable translations [inaudible]?

Laura Fillmore: Well, we want to use the best that's available, and we're not going to be able to translate Dante from Italian into English, but the idea is that it's going to involve the readers and the editors more. We're going to be using the natural language translators that exist now, and based on what they've produced that's going to create fodder for the translators that are going to be involved with the book.

And that's where the publishers come in, too. We're really interested in working with their translators and with their editorial departments. And then what do you do once that translation has happened? I mean, the idea is not that we've got something fully behind a curtain

or something that's going to come out and work fabulously; but what does work and how can we use it to further the work here?

M: In doing business internationally, the implications for that, are you sort of reacting [inaudible] to get things out of there?

M: And get them in German, French, and Spanish and whatever?

Laura Fillmore: Yeah?

M: Typically, in a North American environment you're looking at a very myopic group of people. English is the language of business. But in terms of really opening doors...

Laura Fillmore: They don't think that in Quebec.

M: It's just the interpreter; you know, the practical approach to it.

Laura Fillmore: Yeah, and I think that's why publishers and businesses are so interested in The Global Book, because for one company to do this, to spend the requisite funds to do natural language translation and to research and develop what is the best program and how much human work is required to make it work, if there are multiple funding sources for the project then that information is all shared among the participants so that it becomes a more valuable — becomes one of the values of participating. But the answer doesn't exist today. Keep your eye peeled on October, 1996. Yes?

M: How do you expect people to find information? Say I'm just interested in Nelson Mandela and wanting to find reading and whatnot. I mean, how do you expect people to find your interactive books?

Laura Fillmore: One thing that's been really successful... I kind of see each project as putting down roots. One of the jobs of a link editor, like what Lydia does, is not just to point to places but to initiate correspondence with people that we're linking to. So in Mandela's example we'd write to University of Pennsylvania and say, "You've got a really great site here on Africa, and we're going to link to you," and then they, in turn, link back to us.

With the Mandela project I've found more links to us out on the Net, and these aren't links that we've necessarily solicited, but people are finding us by virtue of the content area; and so I think that accounts for part of it. Also, we'll announce when something's going up.

We try to synergize, and, again, this is the hybrid model where hits on Mandela book result in sales of Mandela book, and hits on the [Chessler] book result on sales of [Chessler]. Bernice is on the best seller list in the *Boston Globe*.

You know, after we put the demo up, there's a synergy between what's available on-line and what's available in print and hard copy. So we try to synergize between what the company is doing in its traditional marketing efforts and what we're doing.

So Random House, for example, is putting out a print ad campaign for *The Practical Guide to Practically Everything* that'll have the URL on it. Time Warner put out a print ad for some of the projects that we're doing that has our URL on it, and their print ad is going to bring customers here to look at the Mandela book. Again, that argues strongly for the collaboration effect, because Miramax Films is going to benefit from Time Warner putting their URL up there. So that's where having a site where a lot of people are coming is a definite value.

If somebody opens up a server tomorrow with the greatest project on earth, if nobody knows he's there that becomes a real challenge; and I think that that's one of the benefits of licensing and collaborating with sites that exist there. And that's a point that I also would like to make in terms of this bipolar linking, this reciprocal linking. Most effective examples of that have come from personal interaction between servers, between people running the servers. "Hey, what you're doing looks really interesting. Let's see if we can link to your map site or link to your conference site." It's not PR and marketing; I don't think PR and marketing work the same way on-line that they do on The Globe. It's a much more personal interaction between people, and that's been pretty effective for us. Sir, over there?

M: How do the ergonomics work on the licensing for *The Practical Guide to Practically Everything*? That was [inaudible] for the right to link to these publications, or I don't understand what happened there.

Laura Fillmore: What happens there is basically defining who's doing what and watching the traffic. We're exchanging information at this point with an eye towards developing subscription and microbilling models. It's nascent licensing models until you're going to keep this up and keep this content up for X amount of time, and that's where it is at this point. We're collaborating with them to watch the statistics, to watch the traffic so that we can then refine the commercial model because everybody understands, again, that it's information that's freely available but not information that's free. Yes?

M: Are you aware of any microbilling models that actually work? I mean, are you doing that right now? It seems to me that the cost of this, implementing a microbilling model would [inaudible] away, especially internationally.

Laura Fillmore: Well, right at the moment, no. I mean, we're not doing it right at the moment. But First Virtual has a microbilling model where they're selling pieces of information. I don't know if Jane Levin is here. She's had information up there.

Any other questions? Yes?

M: What about the futures for things like [inaudible]?

Laura Fillmore: I'm sorry, I can't hear you.

M: The futures? Like, I can see the [inaudible] where you give away the paper book and microbill access for the on-line book.

Laura Fillmore: Yes?

M: That means that you'd have a piece of a laptop that had wireless connection, and if I was to get an international guide for bed & breakfasts there's no way I might have a whole book. It would be the size of a telephone book.

Laura Fillmore: Yes.

M: If you just want to print out just Boston...

Laura Fillmore: Yes...

M: Or just access it in the car, and I just get the information I needed rather than having to page through all of it, then that service [inaudible].

Laura Fillmore: When will it come? In '96, that's what I would predict. I mean, it's virtually there, but I think that it's coming a lot quicker than people generally say it is. I think it will be there in '96. Yes?

M: What kind of strategies are other publishers using? I believe the Electra Press has a book on that called *City of Bricks*.

Laura Fillmore: Yes.

M: [Inaudible] do something similar to that?

Laura Fillmore: Yes, they are. It is a distributed publication with a lot of external links to it, so that would fall into the category of distributed publishing. It is, basically, the same kind of marketing model that they're putting on-line with the expectation that they're going to be selling increased numbers of print books. So that is another example of distributed publishing.

A lot of publishers are using the Net as a marketing vehicle in terms of putting up flap copy and chapters of books and pieces of books so people can see what they're about and can download those.

The distributed model — I know MIT is active in it. Macmillan is doing some of it, and O'Reilly is certainly doing distributed publishing; but what we're doing is working with multiple publishers and companies in terms of exploring the ways that not just one publisher but many publishers can integrate and develop and use the business models for publishing the text itself. Are there any other questions?

I'd like to thank you all for coming, and we'll see you on the Net.

COMMERCE OPENING UP EUROPE! HOW TO GET INVOLVED

MODERATOR
Ivan Pope
Webmedia

SPEAKERS
Stuart Anderton
Future Publishing
Jo Mosaku
Consultant, Future Business Technology Consultancy
Roger Green
Publisher, *Internet Magazine*
Steve Bowbrick
Director, Webmedia

Ivan Pope: [I'd like to start] by basically welcoming you all here and just briefly introducing the speakers. We're going to each talk, and then we're going to invite questions from the floor and try and answer any questions you might have, and discuss what's happening in Europe to some extent.

We've got a rather unrepresentative of Europe bunch of speakers, as we all are based in the U.K., unfortunately. But that's one of the things that happens, logistically. So I'd just like to introduce the people who are going to be speaking, and they are, first, Stuart Anderton.

Stuart Anderton is a publisher of a magazine called *NET* in the U.K., and also an on-line publication called *Future Net*, both Internet publications.

Joe Mosaku, second from the end, is an independent technical consultant based in London, but has a lot of connections in the States.

Roger Green, just arriving here, is also a publisher of a magazine called *Internet* in the U.K., and that's from a publisher called E-Map.

And our main speaker, Steve Bowbrick, is now second from this end. He's the Managing Director of Webmedia in the U.K. It's a Web designing, Web site designing and building company. It's a market leader in the U.K.

And I'm Ivan Pope. I work with Steve, and I'm also Managing Director of a company called WebContent, which is a content developer for the U.K. in the European market.

So I'd just like to introduce Steve Bowbrick, who will take us through the current situation in the European market. Thank you.

Steve Bowbrick: We've just lost the video, it seems.

M: Press I, Steve.

Steve Bowbrick: I'm going to press I. I think it just died, because it fell off the [inaudible]. In the meantime I'll just get started.

My name is Steve Bowbrick. I'm managing director of Webmedia, as Ivan said. Webmedia is a U.K. market-leading Web production house and creative house. And the recent diversification that we've gone through takes Ivan out on to the wing of it, and now Ivan is the Founder/Partner of Webmedia, and he's running a business called WebContent, which is an independent content developer for this weird new medium.

Okay. So there I am, there are my contact details in case you need them. So, I've got a pretty broad topic here, Europe, really. It's an enormous place. I figured, well, what I could do is I could take an approach where I start with just sort of the fall of the Roman Empire, and then work up to the present day. But I think that I'll just cut to the present day.

Now, it's a big place, and I don't know if it's commonly known that there are more people living in Europe than live in the United States of America. There are 300 million people living in the continent of Europe. And I think this number is accurate. The European Union essentially has a population in the area of 300 million people, and it's growing very, very fast. In the most there's 15 countries. There were 12 until quite recently. It's, as you know, not the most coherent place in the world. And I think if you've been watching the events in Yugoslavia over the last year, apart from obviously the human tragedy of it it's had something of a bracing impact on Europeans, because it's been a fairly profound indication for us that even an ancient and relatively stable continent is liable to that kind of disruption.

So I think that there are presently — this is my guess — I'm guessing that there are 30 distinct, viable languages in Europe. I think if there are any linguists in the audience I'd welcome your challenge on that. Now, some of these languages, again, it has to be remembered, don't even use the Latin character set. So, it's a pretty diverse area.

I'm stating the obvious when I say that this market has distinct national identities. And of course, I've just touched on one of the negative impacts of that. But there is — and I don't think I'd be distorting it if I said this — there is an increasing coherence in Europe, and the European Union is the instrument of that. And I come from a country on the northern fringes of Europe where the current government is actually, broadly speaking, anti-European Union and seems to be drifting towards — even as we speak — leaving the European Union, if we listen to the more extreme elements of that government.

I think that I have to emphasize that the business people in Europe believe in the European Union, and believe that it's vital, that it is absolutely vital in our future as businesses and as a community.

The "ancient culture" bit, I suppose that's also kind of obvious, isn't it, if you think about it. But I did feel the need to state that, even if only to contrast it with the culture we're in now, which is where buildings have plaques on them that say "Built in 1948," or something. This is something that's kind of interesting to us. So I want to emphasize that. The ancient cultures have the other "C" word, content, and it wasn't invented until about three years ago, I think it's something like that. But ancient cultures do, broadly speaking, create rich content.

So here's one of the problems that we're up against in Europe. We've got what I've just called here, flippantly, sort of "technology gradient." And broadly speaking, it's north to south in Europe. Much of the wealth gradient is, broadly speaking, north to south in Europe. One of the EU's key functions is to try to even out that gradient to some extent, and there's an interesting conflict going on between the sort of supply-side modernizers in Europe, to the extent that there are very many of them, and the more sort of — what would Americans call it? — a big government approach, which is in, which is how Brussels is typically characterized, especially in Britain by the Major government.

So that work goes on, though, and there is a considerable distributive element to what the European Union does. It's sort of spreading wealth and resources across the continent. And again, that's vital when you're talking about infrastructure issues, which is what we are talking about here, essentially. If we don't have the infrastructure then we don't have a viable medium. And I think that if part of the continent does have a viable infrastructure, as increasingly the north does, then the whole of the continent is impoverished if the rest isn't involved in some way.

Now, the, to say that we have different regulations or requirements in these various nations is a bit of an understatement. We go from the highly liberalized Northern European examples, the U.K. being the leader, I suppose, to countries which I don't think it would be a distortion to say are still operating — although somebody's going, somebody's probably going to throw something at me for saying this — still operating essentially 19th Century models of government and administration in other parts of Europe. And I'm not naming any names here.

So that's an interesting, and it's another element of the gradient that we're dealing with here. And I think that as we try to spread this, this information culture out into the fringes of Europe, this is a significant element that we have to deal with. The uneven national wealth, well, I can roll those last two points into one, I think, in that Europe is a place where per capita income is, I think on average, lower than here in the U.S. This is especially the case of the U.K. now, where we seem to be operating something which I read described as "Hong Kong-ization" the other day, where there's a sense that there's an Asian model of business and government being pursued.

This means that there's less disposable income, especially in those North European countries where the cost of living is also very high. And disposable income is obviously a vital component of everything we're doing. Because that where we're speaking to consumers, I think a lot of people here in this room and a lot of people on the platform are focused on speaking to consumers. When you're speaking to a consumer, naturally disposable income is a vital element, and the assumptions you make about the disposable income of your market here in the U.S. may not carry to the European markets, and certainly won't carry to large parts of Europe.

So let's have a look and try and expand a bit on this regulatory thing. The problem here is that I can't just can't describe one regulatory regime. We're not talking about steel or agriculture here. We're talking about a medium, and we're talking about a medium that operates at very low logical level, the Internet, and which in principal has a reach far beyond any existing medium. So there's an enormous number, it's one of those VEN diagrams of overlapping regulatory regimes that we have to deal with as an industry. And I think obviously the two key ones are media ownership regulation and telecom regulation.

So let me just summarize the points that I've made here. I think that it's clear, and a lot of these points actually that I make in this paper, to the extent that I can, they're Europe-wide. Often the numbers and the figures don't exist for this medium yet, so much of what I'm saying applies very much to the U.K., which, as the largest Internet market outside the U.S., is naturally not 100% representative of the European continent. But I think that it's the feeling in the U.K. that we're very much the vanguard of the European experience.

So the U.K., thanks to Margaret Thatcher, going back quite a way now, does lead in liberalization of telecoms and media ownership. I think the media ownership element, that's a bit moot. I mean, if you look at the Italian model you might find something a bit more liberal, if that's the word. And telecoms, we saw a U.S.-style deregulation. The element that was missing is that the state monopoly, which used to be part of the GPO, the General Post Office, but was spun as British Telecom. The [inaudible] wasn't split up, it wasn't split into local and long distance. Or, on any other terms, it still operates to this day as a monolithic company. But in other ways it was very similar to the U.S. deregulation of telecoms.

The long distance/local split is observed. So you'll see, for instance, that the monopoly regulations in each of those areas are different. So, for instance, until very recently there was no competition in the local loop toll. BT was dominant there. In the last year or so we've begun to see licenses issued — well, the licenses have been issued for ages, actually. We've begun to see players get into the local loop in the U.K. in particular. Now, this is just beginning all across Europe. I think, in particular, the Scandinavian countries are pushing forward to telecom liberalization in a grander way, in a more purposeful way.

So, for instance, there has been competition in the U.K. in long distance for some years now. It's a pretty ruthless business, and the chief competitor to BT, a company called Mercury, which is part of Cable and Wireless, has suffered worse than expected profits in that area.

In the local loop we've got providers like a company called Energess, or a company spun off from the National Grid, the people who operate the electricity pylons in Britain. They've now started getting involved through local partners with local telephony. And the other [inaudible] players there are the cable companies. Now, I've got a slide later on, where I talk in a little bit more detail about cable.

But the key difference here is that in Britain, and in one or two other countries in Europe now, the cable companies can deliver telephony. You can now get your local telephone service from the cable company. You get a new telephone number, and you get what is broadly reckoned to be a slightly worse level of service, but you can get your telephone service from a cable company now. This is important in Britain for the cable companies.

Now, the key thing about this long distance/local split is that actually for U.K. consumers, historically it doesn't have much meaning, because although we know that we're paying more for long distance we're also paying for local calls. Local calls in Britain and in most of Europe are metered, just as long distance calls are. This has a massive impact, as you can imagine, on the consumer take-up of dial-up Internet services. So, for instance, we've seen now with all of the dial-up Internet access providers in Britain, they have, I think — I can't think of an exception — they haven't needed to use time-based billing as a throttle on usage. They just haven't needed it. So this is a completely flat-rate culture in dial-up Internet provision in Britain.

The throttle here is your telephone bill, which can be pretty scary if you're a heavy user in the U.K. Although I don't dial in from home anymore, my own most recent example is that we, typically in the U.K., pay £10 a month, I think that's in the \$15, \$16 a month area for flat-rate Internet access.

So what's that? Telephone bills come quarterly in the U.K., so that's £30 a quarter, about \$45 a quarter. My last telephone bill, when I was dialing in from home, was £300 for a quarter, which is again in the area of \$400, \$450. So that's a significant throttle on on-line use. So you can't assume the free-form surfing experience is going to apply in the European context.

There have been noises for ages about various local loop providers going to flat-rate or free local calls. Although I think that that's the logical endpoint, we're not going to see it for a little while. It's too lucrative an area. And especially now that the telcos are, some businesses are getting into local provision only, then I can't see it applying for a while.

Now, the cable companies will shift this somewhat. The cable companies are already experimenting, to begin with, with cut-rate telephone calls in the local loop, but secondly with free local calls during certain periods — off-peak for instance. At the moment it's just kind of limited, because you tend to be calling between cable subscribers. Now, that's limited; I want to be able to call anybody for nothing if they live local. But I can't do that right now. So there's a pressure to go flat-rate and free in the local loop across Europe, but I don't see it having a significant impact before the end of the century, really. Not across Europe, anyway. Maybe in Britain a bit earlier.

So the cable companies are key here, and in a minute I'll tell you why I think that they find it so attractive, but that's obvious why they find it attractive. They find it pretty attractive here in the U.S., too, to be in telephony.

To finish off with that kind of regulatory aspect, satellite TV has got a huge presence. The beginnings of satellite TV in the U.K. were, if you think about the background, it was against the background of my last point there where — my numbers might be out of date here — the last time I checked cable TV only passed 20% of homes. Now, the take-up is a lot smaller than that, I think as it is in every cable culture. Actually, I don't know what the actual detail

numbers are here in the U.S. are, and you can tell me that, I'm sure. But with cable only passing 20% of homes, satellite got an enormous leg up.

From the beginning the terrain was supposed to be competitive, and it began as being competitive, and there were two players for a little while in satellite TV in Britain. But now there's only one, and it's Rupert Murdoch, and he owns an outfit called BSKYB, which used to be SKY, and then absorbed British Satellite Broadcasting and took the B's and made that bizarre name, BSKYB. So Rupert Murdoch owns satellite TV in Britain, and, as he increasingly does everywhere in the world.

In passing, I know that there are plans to deliver an IP service via the satellite, the Murdoch satellite system. Naturally, satellite is one way, so they've had to come up with a pretty byzantine way of stitching in the return part of the loop, and I noted that's in on the stocks, and I think it's interesting. Now, the other key thing about it, of course, is that it's asymmetrical, because you can squirt about 64K out that way, but only clicks and e-mail out the other way. That's their thinking, anyway. And that I have an obsession with, because I think the assumption that people really only want to send clicks up the line is probably a mistake commercially in the medium term in this industry. I think people are going to want to put richer content back up the pipe.

Okay. So here's a few raw numbers, but these are so hard to — I mean, I tried quite hard to gather these, and I'm quite thankful to Roger in particular here, who gave me some numbers from one of their surveys, which are adopted through this presentation. Guesswork again... About 400,000 hosts in the U.K., that's my latest figure. Highest growth rate in Europe, I'm told. I think that one other country, Denmark, has higher growth in terms of Internet connections. Typically I think we're looking at 10% or 15% growth per month. Is that right, Roger?

Roger Green: Actually, Steve, there's, there's been a big adjustment to the Denmark figures, in the rates [inaudible] survey. So they're not as high as they were, but they're still, they're still sort of number two on the chart.

Steve Bowbrick: Right, number two on the hit rate. But I think to talk to that point, though, is still that the Scandinavians are a very interesting area here, and is pushing forward into these, into the whole sense of the of wired communities and using the Internet. I'm hoping that maybe we've got some Scandinavian folk here who can fill us in on that later on.

So, Britain, it looks is, is preeminent in growth. And I read a survey not long ago, and it was a consumer survey, but it wasn't statistically sound, that suggested one million connected to the Internet in Britain, one million individual users. Now in a population of 55-60 million, that's a pretty good proportion. But I don't know if I trust that, so I'm taking my 200,000 off for caution, and I think we can look at 750,000 - 800,000 in the U.K. Now, taking that as the largest U.K./European market, you can project from that to for instance what Greece has, with a population of only 10 or 15 million.

And now, just as a point there, the fourth host on the AlterNet was in London, 1969, and it was at UCL. It might have been fifth or third, but it was very, very early on. And I think that there is a significant input across the whole history of Internet from Europe and in particular from the U.K., because of that early connection, from the U.K. computer science community. And if you look at the engineering task force and at the other administrative bodies now, you'll see a really significant sprinkling of Europeans there.

Now, this I've called it the "leap frog effect," and I think it has several different meanings here in the European context. I'm just drawing out one element of that here, which I think is important and often neglected, is that this is a bit like — I think people have used this term

when they're talking about developing countries who have to get from a situation of having practically minimum or no infrastructure in telecoms and they need to get forward in the 21st Century here. It's often been said that those countries may do so by going with wireless, with cellular, and with higher technology solutions than [inaudible] and copper.

There's a sort of an equivalent to that in Europe, in that because historically there was a very tiny user base of individual and small business, smaller business Internet users, that meant that there were very few shell accounts. There were plenty of shell accounts in universities, naturally, and in the businesses that needed that. But in the home and in the small business, there were hardly any. So that meant that the consumer access providers — and I don't think I'm distorting this — from the beginning, every single consumer and small business provider, dial-up provider, was selling SLIP or PPP.

Now, I know that that's pretty much the case here too, now. I'm not sure; I mean, we can learn that from you, hopefully. But it really gave the Web a huge boost. It meant that every single dial-up user in Britain — again, there will be a few exceptions there — had access to the Web from day one. Now, if you compare that with global figures, I think that's quite impressive. And it's the case almost all across Europe.

Just in passing, when the "leap frog effect" applied — it's just something that somebody brought up to me just beforehand, which I'll cover in a second in a little bit more detail — is the sense that the commercial on-line services, the majors, the global ones, the U.S. ones, having had no major presence in the U.K., have essentially been bypassed in the U.K. and across Europe. And there, the risk for the on-line services is that they may remain bypassed, and people may cut straight to the Web.

Right, okay. Just a little bit more detail on that cable thing I was telling you about earlier on. There's a lot of lessons that come from cable and the way it's been pushed forward in the U.K. When cable was opened up in very recent years — we're talking only about during the early Eighties — when cable was opened up in the U.K. in particular, the franchises went — I think more than half of the franchises, I'm sure if this is still the case — went to U.S. companies or companies involving U.S. interests or Canadian interests. And that's still the case, I think.

So what happened is, because the regulatory climate suddenly became so much more favorable to those businesses, U.S. and Canadian companies came to Britain and used it as a laboratory for services they were not yet allowed to deliver here in the U.S. Telephony is a perfect example. From the beginning, these companies were allowed to offer telephony. It took a while to wrap that up, but it's now — I don't know of any cable franchises that aren't delivering telephony, though there may be one or two.

So we've seen Britain operated very much as sort of a hothouse for the cable companies, and for their revenue models. Now, the thing about telephony, naturally, is that in the most — I don't know if it's the most — but a very highly debt-laden business, cable TV telephony brings you quarterly revenue very quickly, and for relatively limited or a tiny investment. You've already got the cable going in there. So it's something the cable companies embraced in a big way. I know that they're on the verge of that here in the U.S. too, and it's beginning to happen with regulatory changes here.

Now, what's exciting from our perspective as an industry in Britain and across Europe is that the cable companies have now got their eyes on other high-margin products that they can start to deliver. Now, I think we're seeing this everywhere, or where cable has a significant presence anyway. But it's worth reiterating that cable TV in many markets still hasn't reached its target. In some cases 40 years on from introduction, targets have not been reached in terms of penetration.

In the U.K. this is especially the case. We were supposed to go crazy for cable, and we didn't. We haven't been buying it in a big way. And churn rates are enormous. Free trials are

very popular, cheap trials are very popular, but the churn rates are very high, so people drop those subscriptions early on.

So in an area like that, in a field like that where revenue is so hard to come by, the newer, higher-margin products that the cable companies already know that we want are going to be very important. So there are one or two trials in the U.K. at the most for delivering IP via cable TV networks. And with the cable modems now just coming into mass production on this side of the Atlantic, I think mainly that's going to be really vital. And I think it could make Rupert Murdoch's asymmetric satellite delivery thing look a bit silly.

Okay, let's have a look at how on-line shapes up in the U.K. It's starting with the Web. Eighty access providers is my latest number, but I bet you anything is more than that by now. What do you think, guys?

M: It's 112.

Steve Bowbrick: Okay, 112 access providers in the U.K. The U.K. is, again in this area, absolutely the hothouse. Even large countries like Germany and France have a fraction of that in terms of businesses out there delivering IP over the telephone. Now, if you add in to these largely dial-up providers, those who are delivering specialist corporate account activity, this is a very exciting activity. And it doesn't look like it's hit saturation yet, although we're going to see massive sort of conglomeration, and all those small companies are already beginning to collapse together as they cash out.

Now, I think we've got local dial everywhere. There are probably bits of the U.K. where we don't have local dial, and there are certainly enormous parts of Europe where you don't have local dial. But I think there's local to the Internet everywhere in the U.K. Isolated corners like the Shetland Islands or somewhere may not have local dial yet.

Now, those companies literally spend the... you've got local dial where you live?

M: We've got [inaudible].

Steve Bowbrick: Good, that's good. Oh, and in the Shetlands, too, excellent. That's good. I'll tell you where the Shetland Islands are later on.

So, these, I think as in the U.S., these companies literally span all the way from the tiny mom-and-pop outfits to BC itself, the monolith, who very recently launched a service, a consumer Internet service which is selling direct, and also will resell or will be resold for them around the country. Naturally it took them a long time to come around to it, and all of the small providers were immensely relieved when they saw that BC's offering was really their own offering. You'd think that somebody who literally owns the telephone network could have delivered something exciting from day one, but they were incapable of doing that. So it's been a disappointment.

Now — and also I may be distorting it here — but I think we have V.34 everywhere now. I mean, every provider as V34 and so that's the standard now, I think. V.34 is 28.8 kilobyte per second, dialing in. I'm sure you knew that.

Ivan Pope: Except CompuServe outside London.

Steve Bowbrick: Except CompuServe outside London, okay, where you're still dialing at 2400 or so, or something like that. Yeah, that's right. Okay.

You know the phrase — it's an old phrase, but there again, I think U.S. companies see Europe and [inaudible] in the U.K. as a place where they can conduct experiments, and where

they can regard it as a little bit of a playground with slightly less of a regulatory burden. You know, in some areas there's actually a stiffer regulatory burden, but they may not know that yet.

So in the very recent times we've seen PSI come in and buy EUNetGB. EUNetGB is the British part of EUNet, which is a European-wide, essentially academic — or it started and was founded as an academic network, which has grown to serve corporals as well.

Now, UUNet has bid for another U.K. provider, called [Piepexunipom]. I don't know if that's gone through yet. Has it?

M: Yeah, it's has been accepted, yeah.

Steve Bowbrick: Yeah, it's been accepted, the bid has been accepted, so that's pretty much done and dusted. Now, I'm interested in that deal because of the arrangement that UUNet has with Microsoft in this country is that they deliver up a large portion of their vanguard to Microsoft at certain times of the day for use with the Microsoft Network. I'm interested in seeing if that will go in the U.K., too.

For instance, in the U.K. — and I think in all of Europe right now — the Microsoft Network cannot deliver IP. You can't get through the Microsoft Network to the Web at the moment in the U.K., and I think that this alliance with the purchase of [Piepexunipom] may give them that. But I don't want to prejudge what their intentions are here.

We're seeing similar partnerships going off all over Europe. In Germany, in particular, there is a number of similar partnerships going on and there's room for many more. And I think we haven't begun to see the wave of acquisitions of European properties by established U.S. outfits. And I'm interested to here your input on that kind of movement as we to go the end, as we go to questions and answers.

So... What is there in Europe that is of use to you? Well, let's just summarize those to begin with. I think that Europe has historically been an absolute powerhouse for creative work. In particular, I've just isolated these three areas here.

For design — I'm thinking about graphic design, architecture, fashion, and the rest of it — there's still an enormous resource of those skills in Europe, and their still in enormous demand here in the U.S., as you notice looking around you here. And I think that they will be [in demand] on the Web, in on-line in general.

Advertising. Again, another acknowledged strength of two or three countries inside of Europe is advertising, sophisticated advertising. And I'm particularly gratified to learn from meeting, as I do all the time, U.K. advertising people. They are among the most serious about this medium. They have really done their research, and are committing funds to doing it properly across the board. I'm not saying that every single advertising agency has got anything going on, or even that they've done anything interesting yet, but they're committed to it. And I think this is one of the great strengths of advertising agencies in general in this emerging business, is that they have the resource and the investment, the emotional investment in researching this medium and getting behind it. And they've got people who sit in advertising agencies and don't do anything but research. Right?

And literature. Bill Gates knows that there's a wealth of art in Europe, and he's going around buying it all, he's buying the electronic rights to it all, so that we can have it on the bathroom wall, on that unrolled flat panel that you're going to buy in the future. That's the plan.

So I think that wealth of content that's built up in Europe since — I don't know, 5000 years B.C. or whatever — is an enormous, unplundered stockpile of stuff that we can start to re-purpose and get it onto the Web. I think it's hardly begun as well. You know, in the

Renaissance alone — we could start with the Renaissance, the Renaissance on-line. I can see it now.

Okay, looking a bit deeper, over a bit on the on-line environment to the commercial services. I like to do this comparison. Last year commercial on-line services — this is a bit of distortion, actually, and don't get caught up on this — last year the commercial services in Britain and across Europe broadly were — CompuServe. It's been around since the early Eighties, I think, in Europe, mostly at 2400 in the big cities. It's been slow to get in all the rest of it, but they've been there a long time. And here's the position next year. Some of these are already in place. By next year everyone of these players, and there are more that I'm sure I don't know about, will have a commercial on-line service in Europe. And I've just skipped through them quite quickly, because you may not know about all of them.

Naturally, you know about CompuServe upgrading [the speed] you can get IP across that network; now you can surf the Web by their browser, or the Spry browser that they deliver with the package, or using anything of your choice.

Let's go down the left-hand side. America Online has a deal with [Bertlesman], a giant German headquartered media group. Until all the recent comings together here in the U.S. of media giants, I think they claim to be the third biggest media group in the world. I think they're probably down at fifth or sixth now, but their alliance with America Online brings a wealth of content, including things like BMG and RCA Records, Arista, and a lot of European magazines and book publishers. [Bertlesman] brings that together with America Online's delivery platform. I think that's going to be quite exciting if they can ever get it out, because it's taking a while.

Now Delphi, they've been around for a while, actually, so this is part of my distortion. I think they were here a little longer than I'm suggesting. But their future is as yet undecided, and obviously it's being written. I should have put MCI there, shouldn't I? Because of the recent Murdoch/MCI collusion.

[With the] Microsoft Network, naturally they're in place, but they have that problem with not being able to deliver IP yet.

BT, I told you about that. BT has their own on-line service upcoming. Again, a bit of an unknown quantity right now, and in principle that will be Europe-wide.

Europe Online is a spectacular "euro-pudding," as we like to call it. Something like thirteen, I think, or twelve or thirteen different European media owners have got a chunk of an outfit called Europe Online. [Berde], [Matarachet], [Pierson], and a bunch of others I could never remember. They've got it into their heads that their wealth of content will guarantee them some kind of presence in this new medium, and they've gone and licensed the AT&T Interchange software, formerly Ziff. What was it called? Ziff Interchange, that's right. Yeah, since AT&T has changed. They've licensed that. I think that's a mistake; I don't know what you think, but I think that's a mistake. So they will have the Web down the line sometime, but not for a little while yet, just as they were in the U.S.

U.K. Online is one of many local variants with Olivetti money behind them. There's an Italia Online, for instance, and U.K Online is just one of many variants under that umbrella. It's interesting because it's delivered via the Web, as is, I'm told, the BT product and the Virgin product. Virgin was bound to get in there sooner or later, weren't they? We're going to see an on-line service branded version quite soon. And again, in principle, it's Europe-wide, delivered by the Web.

eWorld, of course. I've put them in brackets because they're a bit sad at the moment. They just essentially folded, but they're turning their product into a Web site, essentially. I think they should have done that a year ago. They've done it now, which is probably about a year too late. A bit sad.

Okay, so that...I think we've got there, let me look, there are one, two, three, four, five, six, seven, eight, nine, ten, eleven players in European on-line [services], not counting the local variants. No, ten. Ten plus the local variants. That's an enormous number of an enormous richness of on-line services out there. And the content of what I was saying earlier on, every single one of them may have missed the boat, which is tragic, because people are already wholesale surfing the Web.

So who's actually developing content in this market? I've got three categories, which are a bit arbitrary, but let me go through them. I just picked out a couple here, the *Telegraph* and the BBC, and names that you might have heard of.

The *Daily Telegraph* is a national daily paper in the U.K. They have a service called The Electronic Telegraph, which is a Web service. In many ways I'm critical of it because it's a fairly — well, it's a terrible thing to say, I suppose, but it's a fairly crude re-purposing of their daily content, and has not brought to, or not quite yet, brought anything of the Web to that content. But I think that's changing as they go along.

The BBC has a limited presence out there on the Web right now, and I mention them because I think they're interesting, given their public service. What they can do on the Web seems so far to have been held back somewhat. And I think that I'd love to see the BBC deliver something really rich and global, much as they have done in radio for years. But they haven't been able to do that yet, for whatever reason.

We've also got a couple of other media owners on the platform here. Roger from E-Map, a magazine publisher, and then Stuart from another magazine publisher. So these are U.K. players, and naturally there are the same types of outfits across Europe that are doing this. The corporals I've mentioned here; Lloyds Bank has looked at it, so I did [inaudible], I'd be lying to you if I told you that I didn't put them in there because they are clients of ours. They are clients of Webmedia, so I put them in there.

[Tape change]

Steve Bowbrick: Because this is what we're taking them towards, and what businesses like us are taking them towards — actually delivering viable, useful, stand-alone content via that unique URL www.luftansaco.uk, whatever. And that's the model that we're trying to move towards there. And the agencies I've mentioned that have global presence, [Coodean] and Ogilvy & Mather are already delivering — [Coodean] are actually a subsidiary KHBB — are delivering lots of content on-line for their clients.

Other players on the Internet are CIA Media Network, [Lohow & Spink] and a bunch of others in the U.K., all major ad players.

Now, their model is a different matter. How are they approaching this is something which we as an industry are very sensitive to in the U.K.; and I think that again I've used the same three categories, so let's look at how in each case they are approaching this medium.

I think, given their investment in the Web, that we can probably exclude the media owners on the platform here from this category. But the media owners broadly, especially the ones I described earlier, seem to think of the Web as like a television without rules. There's no regulation yet, so let's just use it like TV, let's use it as a one-way medium, let's squirt the same kind of content we're already delivering out via this new channel. We're seeing that here in the U.S., too, but we're also seeing — because there's a lead in this country — you're also seeing the enrichment of that content with Web's specific material. It hasn't quite happened yet across Europe.

The corporates. They've still got the billboards on the superhighway, on the "information superhighway" model. Our challenge as an industry, working with corporals, is to

convince them that what they have is something much richer. What they have is the opportunity to speak with their customer base and with prospects, and to have a conversation with them in a completely unparalleled way, in a way they could never have done before. And while we're just putting out banner style ads that lead to a page of more banners and text specs for the car, or whatever it is, then I think we're not exploiting the full potential of this medium. We need to be using it to have a conversation with the visitors to our sites. This is my priority one. But that's just beginning.

So again, for the agencies, the problem with their model... You can see what I've done here is isolated the problem with each sector's model, in that they are often coming from the perspective of a mass market. If you have been out marketing consumer supermarket goods, it must be very hard to get out of that mind-set. We're working very hard to do that and to get people around to the idea of one-to-one communications.

Again, I think that will come up in the Q&A, I'm sure. And I've used up way too much time, so I'm going to try and get a little bit faster here.

Cultural differences. Big, big point, isn't it? I've just isolated four here, and they're pretty prosaic. I'm not even beginning to talk about real cultural differences here; I'm talking about cultural differences that are out in this medium.

In the media landscape in Europe, this doesn't apply, But broadly, and especially in the U.K., it has a very deeply-embedded public service [inaudible]. So, for instance, the BBC is the perfect example here. There's a sense that the people perceive, broadly speaking, the BBC and other media owners across Europe as delivering a public service, delivering something which is historically paid for out of your taxes. So that's very deeply embedded. It needs to be worked with gently. The "this is where the advertising leads" model may need some work, because if ads are too dominant in your Web site, or if your commercial message is too dominant, you may find that it falls on unreceptive ears.

Now, I have said that there's no concept of "paid-for" programming. The idea that the advertiser may own the content, which is something which has a much greater presence here in the U.S. — that doesn't have any currency, really, in the U.K. or in Europe. It's been the case that the media owner owns the programming, and the advertiser gets the slot parceled out by the 30-second chunk. Now, that is a model which the Web, obviously, completely overturns; and what I say to those corporate clients, like I was telling you just now, is that this is paid-for programming. You own the channel, you can deliver anything you like out through that channel, and you own it forever. Now, that's something they're just beginning to get their hands around. But the consumers may take a little bit longer to adjust to that.

Weird funding models. We really do have some weird funding models for the media in the U.K. I'm really fond of saying "if I told you that to watch the TV in Britain you had to pay, you had to buy a license from the government and that it costs \$150 or thereabouts, and that there are people in detector vans going around in the streets with these fake aerials on the roof spinning around, supposedly detecting your TV, and they claim to know what you're watching and everything..." It's really scary." We have this bureaucracy dedicated to taking the license fee from users. And the license fee pays for the BBC. It's called a television license, but it also pays for the radio. That's weird. I can never get my hands around that at all.

And there are a bunch of equally byzantine and strange funding models across Europe that you're going to have work with. Now, a great thing about the Web is that you start from scratch. I don't think there is anybody in Europe who operates a modem license, that's probably a hoax. But that's the equivalent of what we're talking about here. To have a TV in Britain, you have to have a license.

Okay. We've got a cynical audience. I think I've brought along four particularly good representatives of that audience here today. You know, it's only partly because two of them are

press. They're — cynical is probably the wrong word. Maybe skeptical, maybe overly-critical, maybe a bit resistant to your wiles, is something I think you're going to find, especially in the U.K. I know it's a bit of a classic of the English and British temperament, but I think it's also fairly widespread across Europe. You may not find that you're so unquestioningly received.

All right. I'm just going to work around to a finish here. So what do we actually need in Europe, what do we need from the U.S.? This is like a cry from the heart, you know. These are things we really want. Okay? And we know that you've got it. So we want it now. Okay?

So we want bandwidth. Now, we've got bandwidth, there's bandwidth all over the place in Europe. The Webmedia Web server lives behind a T-1. Now, that's pretty fast. But the infrastructure isn't there. We need more bandwidth. We need... Now, BT owns it all, they've got all the fiber under the ground, but they're not delivering it fast enough and they need a bit of a kick. So we need some people across Europe to be bringing bandwidth with them. They can buy it and license it from the people who already own it. But we need interesting entrepreneurial ideas related to bandwidth and infrastructure now, please. Okay? And I'll be giving our cards afterwards if you want to come and deliver.

Now, technical know-how. Although, as I said, the Europeans started significant input into the Internet and it's history, we know that the focus is here in the U.S., and we'd like to get a hold of that. Again, we want, we don't want the Marshall Plan, we want, we want to buy it, and we're ready. Okay?

Now, the entrepreneurial drive is something which is not uncommon to this business. This is not peculiar to this business. It's something that we need, and we can get a hold of it from you in partnerships. So that's — come on over. And aptitude is the key. I mean, we're just spending time at this event, and the aptitude of this industry is really desirable for the industry. And we'd like to see more of that in the U.S. — in the U.K., and in Europe.

But what do you get in return? Okay, you get the creativity I was telling you about earlier on, which is a not inconsiderable resource. The EU is 300 million people, not all of whom are creative. I haven't met all of them, but some of them are really creative.

Audiences — there's a lot of them. I've kind of restated myself there, haven't I? The EU has 600 million eyeballs, and growing. And with fifteen countries now, we can expect a lot more soon.

And also the content itself. This is already on the Web in Europe, so look for European resources on the Web. Next time you're sitting in front of *Yahoo* or something, look for European resources. There's already loads of exciting stuff out there. What it often lacks is a business model. It's great stuff you've seen that here in the U.S., too... what it often lacks is some sense of how to get this to people, how to market it and how to package it.

So this is what you get if you come over, essentially. I think that this market is growing. The population is growing, just as it does here in the U.S., but it's got the unique property, I think — which the U.S. broadly doesn't have — of actually growing physically. It's moving East. We've got the tragic sort of bottleneck of Yugoslavia right now, for, not just for business, but for European culture and history; but in the market, Europe is still growing East. And you wait till it absorbs Russia. That's going to be an extraordinary moment. It may be a few years off, but I anticipate that the EU will be 20 countries by 2000.

This makes it, I think, the most diverse market in the world. I'm sure that the folks from the various Asian tigers would tell us otherwise, but I don't think of that as a significant or a sufficiently coherent market yet. Europe is a much more coherent market, and very, very diverse in it's needs. So if you have a mind to the kind of niche product that works on the Web, Europe is a great place to work that through.

The trade barriers are effectively down. There is a local resistance to this; you try importing a car into Greece. There are local problems here, but it is broadly an open market, and it is immensely investment-friendly, especially in my corner of it.

So this is how you can actually do it. These are the practical things you can do. You can get partnerships going. Now, that doesn't mean buying a U.K. or a European company, it means something more sophisticated than that. If you want to you can get a partnership going, you can license your content product for Europe, or for any other territory for that matter. But when I look at *Yahoo* and I see the ad across the front there for Saturn or something, it really galls me. It's meaningless to me. I can't buy a Saturn in the U.K. There's a terrible gaping hole there. License your content to someone in the U.K. who can make sense of it for you.

There's lots of content. Let's source your European content. When you want to speak to Europeans, get the content in Europe. I know that's stating the obvious to some extent, isn't it? But there's lots of it, and there's people prepared to do it.

And get yourself a distributor. If what you have is a product — and I don't mean a software product or a hardware product — if what you have is a product, a packageable, shrinkwrapable, get-your-hand-aroundable product, find somebody in the U.K. who can OEM it or distribute it for you, or in the rest of Europe. I keep saying U.K., don't I? I'm a terrible chauvinist.

To finish off I'm going to tell you about this trade body. It's the IDA. I'm on a committee for this outfit, and so is Stuart on the end there. It's a trade body for the commercial Web. It actually comes — the name and the original IDA comes from the IDA here in the U.S., started up by a fellow called Joe Andrew, who's now with GNP Computers. He started the idea of the IDA in the U.S. I think the U.S. is too big a country so far, though, and the body in the U.S. hasn't achieved the focus it needs yet.

Over in the U.K. it's much more compact, it's a tiny little country, about 800 miles from top to toe, so we've been able to bring the industry together much more quickly. And these are the three groups that we're speaking to in the IDA: the media owners, the production houses, and content developers, [as well as] the ad agencies, and they're already very much a part of that. All of the significant players have joined up. So if you'd like to know about that in particular you can ask me or Stuart on the end of the panel there afterwards, or during the Q&A.

And with that I'd like to finish up, and thanks for your attention.

Ivan Pope: Okay. Each member of the panel is just going to take a few minutes to give their perspective after Steve's comprehensive [analysis] of the situation in Europe, and then we'll invite questions from the floor. So if we could have Stuart Anderton first, from Future Publishing.

Stuart Anderton: Is this working? Yeah? All right. I'm going to be an awful lot shorter than Steve. And I should also point out that I was only asked to join this panel a half an hour before we started, so it's not going to be too coherent either.

My name is Stuart Anderton, and I work for a company called Future Publishing, which is the magazine publishing arm of the Pierson Group, Financial Times, Penguin Books, Adams & Wesley and so forth. And we also publish two Internet-based magazines, or magazines about the Internet, which are three of the best selling magazines in Europe. And we also run a Web site, FutureNet, which is in the top five Web sites in Europe and in other either the busiest or the second busiest commercial Web sites in Europe. It's difficult to say without actual figures. That's where I'm coming from.

I'd just like to re-emphasize a couple of things that Steve said, not to disagree with any of it, really. One thing that I would emphasize quite strongly is that certainly northern

Europeans, British, are much more cynical about the Internet and the implications of the Net than it would appear that most Americans are, as far as we can judge from *Wired* magazine, anyway.

The concepts like Netscape 2.0 are considered pretty laughable in the U.K. People find that stuff amusing. And the implication of that is that, well, the Internet may be a global medium, literally, in the sense that you can communicate one part of the globe to any other, but it is not a global medium in terms of content. *Wired* found that out the hard way in producing the U.K. version of the print magazine, which despite an absolutely unprecedented media blast when it launched has not done very well.

And something I come across day-to-day in talking to companies which are multinational companies, is sort of saying, "Well, when are you getting on Web in the U.K.?" And they say, "Well, we're on the Web in the U.S." And that just doesn't work, the content is wrong, and also just such technical things as the bandwidth is wrong. The bandwidth between the U.K. and the U.S. is extremely poor. Steve may have a 2 megabyte line into his office, but there's only barely 2 megabits across the Atlantic. So the U.S. sites run extremely slowly from the U.K. So it's not enough to just put one central resource up; you need to mirror, at the very least.

The main thing that's going to happen in Europe next year is there's going to be absolute all-out war on the service provision and on-line services market. As Steve said, basically last year there was CompuServe, there was also eWorld, but nobody signed up for that. The biggest single player for a long time was actually a dial-up SLIP PPP, an access provider called Demon, which has around 40,000-50,000 users in the U.K. That compares to CompuServe's probably 150,000. So you see the proportion of people with direct Internet access is very much higher.

But the overall level of penetration is actually very low. Next year the marketing budgets of the companies which are trying to get trans-European on-line services together are huge. And so Richard and myself are wringing our hands, really, at the prospect. But come January or February of next year AOL will be launching, Europe Online will be launching. Much of the network at the moment in the U.K. and Europe in general is not a viable service, but it will become so probably by the middle of next year, and there will be an immense battle for people's on-line Eurodollars.

I think, really, the only other thing to say is that the state of Web development in the U.K. and in Europe in general is behind that in the U.S., but only behind on quite a short curve. We'll be up with you soon, as I'm assuming [inaudible] growing. But we're working with very limited resources compared to what's available in the U.S. My Web site operates on probably less than 10% of the resources of something like *Hot Wired*, which is who we're trying to compete with. And I think that's true broadly across Europe, which I guess you could say gives you an opportunity to break into the U.K. and the European markets while our resourcing is still light.

That's about all I have to say.

Ivan Pope: Thank you, Stuart. And now I'd like Joe to say a few words.

Jo Mosaku: Right. I'll introduce myself. I'm an independent consultant. I am not going to plug any particular company while I'm here, apart from myself. Basically, the U.K. scene in respect to the U.S. scene is very different in terms of attitude. Business leaders in the U.K. are now coming around to the idea that the Internet is actually a legitimate medium. But it hasn't been so, well, for the last year or so, and I think in the next year we'll see more activity in terms of attitude towards the Net being something that you can actually use, and not being something that's a throwaway fad, a passing phase.

The companies I deal with see me as their eyes and ears, and I spend a lot of my time in the U.S., primarily researching what's going on here. And basically Steve mentioned that Europe has a lot of creativity. We have a lot of creativity, but we seem to lack technical creativity, which I think is vastly prevalent in the U.S., where they have a much more sophisticated uses of technology, and where it's been put in databases to the back-end of Web site searches.

We operate from Europe, and my [inaudible] is primarily in the U.K. And that is something which I think we need to explore further. We need, at least, to have more of the technical creativity from the U.S. perspective coming to Europe. And maybe we can export to you some of our traditional creativity, that in the other direction.

I'd like to add further that the attitude to on-line services is very different. The French have had a system for a long time called MFL, and so the concept of the Internet — again it's a predominantly "U.S-centric" medium to them in a foreign language to them. You know, a lot of the people in the U.S. are producing multi-lingual Web sites, and this, again, about focusing on marketing to Europe; you have to bear in mind that European people are quite proud of their cultures and their languages, and they find it a bit patronizing to click and see *Yahoo*, and have an ad for a Saturn or some computer distributor in the U.S., in Ohio or whatever. And this doesn't make a lot of sense to them. It provides them with a reticence to get involved with this U.S-centric medium.

They want — they need more focus for their own local markets, so if you are from a multinational organization, get involved with the local people to actually provide you with the expertise and the knowledge of the local markets so that you can actually reach people who will then be more receptive to what your message is.

About that again; I mean, the advertising agencies have been looking at this in the U.K., and there have been some interesting projects that have been put around them. Ogilvy & Mather have done a thing about six months ago with Guinness. I'm not sure if you're familiar with what Guinness is — it's the Irish drink, it's brown, dark, with a creamy head — where they distribute to the screen-saver on their Web site, which I've lost count of... [Steve], You know, you're the man with the statistics.

Steve Bowbrick: They have more downloads, I understand, than people could have conceivably accessed the Web site.

Jo Mosaku: There you go. So that was a great marketing campaign where they distributed for an alcoholic beverage. And there are restraints on where you can actually advertise alcohol in the U.K. as well. So again, being the Net where there are very few rules and regulations, it was an interesting exercise.

So I think we have this creativity in the U.K., but there is a lack of, as was said, resources. And I consider it to be the artificial high price of products of hardware and software, and people don't actually own the kit to get on-line, or they see it as just far too an expensive proposition for them to actually get involved in a purchase of equipment like that, especially for personal home use. This, again, is a problem associated with the EU, as it's called now. As a single market it still operates, I think, very much as very separate small markets, and not one unified market. Again, that has to do with historical, cultural, and various issues, and just the nature of the way people want to protect their own local markets.

So I think the U.S. companies perhaps are very aggressive in marketing their products in Europe, but they have to bring their price down and start to look at Europe as a bigger market, at 300 million, so we should be getting the economies of scale. But we're tailored to move out, to getting that way. You know, there are local sensitivities.

And I want to comment further on a few other things, like entrepreneurship and marketing. These things are not as sophisticated as they are here. I mean, maybe not so much sophisticated; I think Americans tend to have more of the drive the enthusiasm for the new, for technology, which is lacking. We need more of you to come over and fuse these people in Europe. I spend my time rushing backwards and forwards, and they think I'm a mad person, saying in the Net you can do these wonderful things. And they just don't buy it, they don't see it. It's probably part of the education system in Europe, where technology is not promoted as being something to aspire to; I think it's deeply in the U.S. culture that technology is something we want to have, especially in business where it's seen as a competitive advantage having the quickest, the fastest database computer or whatever so you can deliver to your market quicker than your competitor. This is the way business operates in the U.S.

And in the U.K., there are companies who are focused and do have that attitude, but in the main there's a reluctance to think that way. And I think we need, again, more of you to come over and exchange your ideas with the people there. I mean, I'm a one-man band running backwards and forwards. I can't shape the opinions of 300 million people by myself. And I think the idea that Steve mentioned earlier about strategic alliances — there's very much a huge market for that, and people are waiting and ready to do business with the U.S., but in terms of — not master-slave, but more as partners; because there are a few huge conglomerates out there who are pretty aggressive, and are prepared to squash their partners. I think a more friendly partnership would reap dividends within Europe.

I think, before I start repeating myself, I'll let someone else take over.

Ivan Pope: Thank you, Joe. And then I'd like Roger to introduce himself.

Roger Green: Thank you, Ivan. Thanks, Joe. I suppose I'm the final speaker from this panel at this time. Is this microphone on?

M: Yes.

Roger Green: Okay, yeah. It's just that I couldn't quite hear myself. I'm sorry, unlike Larry Ellison we'll forgot the dry ice for this presentation, for any of you that saw Oracle the other night. I'd like to summarize, really, some of the things that have been said and just inject a few of my own thoughts or prejudices, or whatever you care to call them, and finish up with some practical suggestions that you can take home or back to the office and do later today or tomorrow to kind of increase your understanding of the European market.

Now, the first thing I'd like to say, and in fact Joe did allude to this, is that you've been presented this afternoon with a very kind of a British-based — or in Joe's case, British and U.S.-based — panel. Don't forget that there are some other countries out there. In particular, if you want to see some distinctions, and some big distinctions to what we've been talking about, look at France or go to France and see what's happening there. At the moment, France is still, and has long been, the most wired nation in Europe. For many years now, many, many households who have had access to France's telecom Minitel service, and that gives a whole different perspective on the use of on-line services. It's the other end of the spectrum from Britain, where there hasn't been much of a tradition of on-line service use until recent years.

So having prefaced my remarks by saying "stop listening to us Brits or part-Brits," then I'll go on and talk to you with a British point of view.

First of all, just to explain, I'm the publisher in the U.K. of this magazine, *Internet* magazine, one of the top-selling titles in the U.K. (It's a private joke there with my colleague on the end of the table.) And in the course of my activities as a publisher of the magazine for the

last year, we've had the pleasure of working with a number of well-known Internet market companies such as IBM, Silicon Graphics, CompuServe, and Netscape, and as we help and work to develop the market in the U.K. it's become clear that it has certain characteristics, and there are certain things about the U.K. market. Now, remember, this is one which is probably more similar to your own than many of the others. It's certainly more similar than France, and probably more similar than Germany. But there are some distinctions between the way things are in the U.K.

Now, the first thing that surprises people, especially people I've been talking to here, is that the U.K. Internet, or the commercial Internet market in the U.K., is growing incredibly fast. There is a great deal of activity there. Steve mentioned the large number of access providers that are there currently; when I left London on Sunday there were 112, there are probably about 115 by now, because it's been growing that rapidly over the last few weeks.

Now, it doesn't mean that they are all substantial and successful organizations, because as London reports coming out in a couple of weeks will say, probably most of those companies have got 200 or fewer customers. And it's estimated in the U.K. that if you want to be successful as a commercial access provider, and that's your main business, you need about 20,000 customers. So some of them have got a long way to go.

The other characteristic, though, and something that we kind of expect to come — I'm referring back to one of Steve's slides about what are we looking for from the United States — [is that] we're looking for some handy, instant tips about how to run a decent Internet provider service, because of the 110 — or a few of the 110 — that have got more than 200 customers, it has to be said not many of them are very good. And indeed, it should also be said that some of the are quite useless. You would be shocked if you were used to the standard of, not only the standard of the technical service but also the standard of the marketing, the standard of the subscription renewal programs and so on, that you're used to here. You'd be shocked at the way it is in the U.K. at the moment.

And even from the technical point of view, one of the things that we do in our magazine which isn't done here — perhaps because it doesn't need to be done, and perhaps here it's assumed that provider services work — one of the things we do in our magazine and have done in the past couple of months is to measure the services. So every 20 minutes, seven days a week, around the clock, all of the main providers, and certainly all of them who have got more than 200 customers, are dialed from our test labs. And, well we start of testing whether there's a connection or not, and anyone who's interested can look at our latest set of charts. And for most of them, they go like that. Most of them are like that.

So, the market is very, very fast-growing, there's a lot of action there, there's going to be great scope for it to be done properly, or at least in a way that you would recognize as properly.

Other indications of action in the U.K. are "cyber cafes." Arguably the world's first cyber cafe was opened in London about a year ago. There are now about 25 in the U.K. Again, as I think as Steve mentioned, we're talking about a fairly small country, about 800 miles from end to end, with a lot of activity, a lot of public awareness and so on.

So if you're a marketer of Internet-related products or services, you might write, and we would invite you, of course, to come and sell your wares there.

I imagine that many of you have come to find out some facts and figures about the European market. One of the things that you will rapidly discover, and as I was saying to you... A very honest consultant who has been calling me over the past few weeks is working on a business plan for a famous name Internet software company not presently active in the U.K. There is hardly any information; there's hardly any hard information about the market available in the U.K., let alone some of the other countries which have still to catch up.

If you are looking for information about what's happening, I invite you to contact me or to contact Stuart, who's the publisher of another respected publication there. We can tell you about the market. Indeed, my particular magazine has, because there's a dearth of research, we've produced some ourselves about what's happening in the U.K., because we were being asked so often for it.

If I can just pull out a few of the distinctions between America and Europe in the interest of kind of summing up... As Steve mentioned early on, in the U.K. and probably in other countries where Internet use becomes widespread, people who are dialing up from home to use the Internet are going to constantly be under the pressure of knowing that every moment they're on they're spending money, despite the flat-rate charging from the providers. Now, that's going to make users in Europe very impatient with sites created in countries such as this one, where people don't have such time pressures on them.

And of course, the flip side of this is that the content that gets created in Europe by people who are working within that environment are likely to come up with more, certainly faster, more rapid-fire experiences, and maybe ultimately more satisfying experiences than those created here, where bandwidth to the home is cheap and almost cost-free.

And there's a very good parallel that I draw for this, which is that — hope you agree that it's adequate — which is that for many years in eastern Europe some of the very best computer programming was done, because until the recent years, people in eastern Europe have far scarcer computer resources to work for, or work with. They had smaller memories in their computers, they had less storage, and so they were tending to produce very, very tight code, they were not producing the “bloat” kind of applications that one began to see with the rise of Windows. So because of those constraints, I think people in Europe are going to produce often more interesting, and certainly more end-user focused applications, ones that aren't based on the assumption that you've got to have a giant graphic which has got pictures of all of the activities of your enterprise.

Another distinction to draw, as Steve said, is that on-line services are unknown in Europe, apart from CompuServe. So that means that people are going kind of straight to the Web, and they're avoiding proprietary interfaces.

Another aspect of that, of course, is that because publishers and content owners in Europe have been kind of behind what's happening here, you tend not to find publishers' sites from Europe crammed with legacy content, as you might call it, which has been shoveled on over the past few years in the way it has here. And I think you'll find that some of the more enlightened media owners, if we call them that, will understand that there are different ways to work on the Internet than simply to expect people to want to wade through your “shovelware.”

So, certainly it's all Web, really. I share the cynical view that not many, if any, of those proprietary on-line services are going to work. Like Stuart, I'll quite happily accept the money from the promotional budgets. I suppose that does sound rather cynical, but really, the more aware on-line service providers — and notably Microsoft Network in Europe — understand this, and it's one reason why the Microsoft Network in Europe is not likely to hit it's stride until the middle of next year, because the people responsible for it in Europe understand the landscape, where there's no culture, really, of using an on-line service. And over here, of course, people might be persuaded to switch from America Online to Microsoft Network because they tend to think in those terms. In Europe they will not.

So, just very briefly about one or two other things for the future, then I'll give you a list of things to do when you go back to increase your understanding of that rich tapestry that is Europe today.

On a more kind of upbeat note, there is a huge potential for development tools in Europe. If you happen to be connected with a company which produces such tools, or is intending to do business across the Atlantic, get distribution for them, because there is so much activity there. And picking up on one of Stuart's point, publishers generally in the U.K. tend to work with fewer people while attempting to achieve the same results.

[Tape change]

Roger Green:...to make the production of Web Pages more efficient. So there's a huge potential there, so do make your way across the Atlantic at the earliest opportunity. I would warn you to look to Europe for innovations. You, you really should take a look at what's going on there because of the constraints I mentioned; people are going to have to be creative. You know, I think you should look to Europe for kind of the new media empires, which is a phrase coined by our moderators sometime back on a radio program. Look to Europe for some very exciting development.

Finally, here are some things to do to help you look to Europe. First of all, if the show is still open, there are a couple of really interesting products, which was nice to see. One in particular is a Bitstream product that's going to see the light of day in the first quarter of next year, which will make — they say, but I would like to disbelieve them — it will make it much easier for Web browsers to display nonstandard ASCII characters, the ones that Steve referred to early on in his presentation. There's a lot of people in the Baltic, in Greece, in many countries that use unusual characters. Britain's got a few, Germany's got several; In France it's very limiting at the moment as to what can be seen in a simple text application. Bitstream has got a nice solution to that. So if you haven't seen that, go and look at it. If you have seen it, do support it, it will help make the Web more international.

Somebody — and I'm afraid to say I've forgotten their name, it's in a box of releases somewhere — there's somebody, at least one company here, with a multi-lingual browser. Take a look at that, support it if it's any good.

M: [Alice].

Roger Green: [Alice] from....

M: Montreal.

Roger Green: From Montreal, the former Canada, I think, that's — no, sorry, it still is Canada, isn't it? It still is Canada.

Okay, something else to do. If I assume everybody here has Internet access, find five interesting European sites and put them in your hot list, and look at them regularly and see how they develop. I think that the Europeans are going to learn by being a bit lazy. You get a chance to learn from other people's mistakes, and many of them will.

Another thing to do, if you're not familiar with it, if you use a Windows PC, download the screen-saver. It's a fabulous example of European creativity, and I'm not just saying that because a guy that did it used to work for our company. But take a look at that, it's an excellent piece of marketing; an excellent promotion for a dark drink with the white stuff on top, as Joe put it.

Then, finally, things to do next time you are in London. Call me, call Joe, call any of us and we'd be happy to show you around or at least talk to you about what's happening, because it's getting pretty exciting there— although sometimes I wish it wasn't quite so exciting as it is.

Thanks very much.

Ivan Pope: I'm just going to wrap up really quick here, and then see if there are any questions. I just want to end on a really bullish note to say there's a lot of information there, there's a lot of ideas about what's going on in Europe. It's incredibly exciting, and I want to be really upbeat about it. It's incredibly exciting in Europe at the moment. It's like we're on either the up or the down parts of a roller coaster. We're following your car on the roller coaster, and you're up and we're going down, and it's all over the place, as I'm sure you know from here. But it is very, very dramatic and exciting.

We do want a lot of things from you. Obviously, we want your technology. We want your experience of setting up for and running the technology. We want your bandwidth, we want your software. We do have a lot to offer in return.

No one's actually mentioned this. I just want to mention this, for what it's worth. I don't know if it's worth anything. But we have a very close sort of emotional connection with the WorldWide Web insofar as it was actually invented after a European institution based in Switzerland, an institution that is run by various European countries. And by an Englishman. I mean, I know that Englishman is now working in the States, but for what it's worth it's always said that we're very good in Britain at exploiting them. And, there you go. But we do have a very close emotional connection with the Web, and we think we're doing some very exciting things.

Something that was just touched on briefly; we want your capital. We're very bad entrepreneurs in Europe. From my perspective, it's very difficult to enthuse people with the potential and the possibility that we all know is there. So we want your capital to come and get projects running in Europe. Steve alluded to the Marshall Plan earlier, and he said, "We don't want a Marshall Plan." But I think my understanding of the Marshall Plan is that it was actually a loan, and we did pay it all back in the end. So don't worry about that, we do have quite a lot of money over in Europe and you will get it all back in spades.

So I'd like to just now throw it open and see if we can get any questions for the panel, anyone you want to throw a question at and come to some further points. Yes, in the back there?

W: You haven't talked much about language. I realize you're all from the U.K. How important is language and the different languages in Europe in getting such wide acceptance?

[Panel]: I touched on that earlier, actually, and it is extremely important. I mean, to a French person, to read something on the Web in English is an abomination. And I mean, the French...

M: If, if I may just jump in, I just want to make one quick point, because I'm based in Paris, and it's not an abomination. They just won't read it.

[Panel]: There you go.

M: But on the other hand, what you need to realize is, I don't know what you know about the [inaudible], but it's a billion dollar in revenues for people that are putting [inaudible]. And I'm just talking about people calling up [inaudible]. So there's a well-developed, highly profitable, extremely interesting wealth of information on what people will pay for in terms of [inaudible] in just one market. There are 6 million people, and that's a technology that's 2400 baud under that.

When you look at what the Web can do, and what the new technologies can do, there's a huge increase in user ability and usefulness. But there's a tremendous [inaudible], in fact an openness, I would say, on one level, the level of a consumer paying to access information, and paying a lot. So understanding the variations in Europe is actually a complicated and tricky thing because of this diversity, and because the English [inaudible]. But I would not rule out the opportunity to understanding.

[Panel]: Yes, I want to say I suppose absolutely that's why [inaudible] with people in those countries get that local knowledge and that local translation. That will be a very interesting sort or project. Yes?

M: If you can, let me just, [inaudible].

[Panel]: I did try in very limited way to touch on this. Because we're an absolutely useless European panel. Obviously we're an English panel. But we're... If you take a bottom-up approach, if you scour Europe for the rich content that's already there and then absorb, exploit, whatever, that content, then essentially this isn't a problem and the problem goes away. But if you take a centralized CompuServe approach — which I know is breaking down now — but the proprietary approach, and then try to deliver your existing caller content into multiple languages, then that will break. Because it's just too top-heavy, it's just too unwieldy. To take the bottom-up approach, it's very Internet, it's very Web.

M: Ivan?

Ivan Pope: Yes?

M: [Inaudible] doing that?

[Panel]: Yeah.

Ivan Pope: Yeah, yeah. And the Olivetti project, too, U.K. Online, Italia Online, all of those yeah. So, yeah, all of the [inaudible] are focused on delivering their content via the Web. Broadly speaking, that's what they're doing.

M: There's a kind of a fallacy, because what everybody's saying here, from Europe, is that the European market wants content, but they don't want content relative to the U.S. They want language from the [inaudible], not English-based. They're more towards that, and that foreign language is an on-line type of service rather than an open Internet. So I think it's a fallacy here. I don't know what your views on that are.

[Panel]: Well, I'll answer that. I was in Paris a few months ago, sitting in an "Internet cafe," browsing the Web. Now, it's quite strange to be browsing the Web in France, and the text coming up in English. There are a lot of French sites now in French, but primarily 99% of the content on the Internet is in English. So I think there has to be an appreciation that not everyone does speak English.

M: And the thing is, it's the AOL that's going into Europe, and Europe Online. The question is that when those on-line services — not Web-based services, but on-line services— become strong enough to serve the market there, do you think that people will access the Internet and

go into on-line? Or do you think not [inaudible], because all the discussion leads to [the fact] that the European consumer would like something tailored to him, in his own language and relevant to him, without seeing the Saturn.

[Panel]: The fallacy is not....

M: [inaudible]

[Panel]: The fallacy is slightly different. I think the fallacy is thinking that the only kind of valid aggregation of content, or on-line community is an on-line service. We're seeing perfectly valid and useful and interesting content aggregators, community-based approaches, what Bill Gates calls "branded communities" emerging on the Web.

[Panel]: Yeah, I think what the point is whether the distinction between the on-line service and a Web service will break down faster in Europe than it will, perhaps, over here. There isn't the 6 million people in Europe already signed up on on-line services. There's not that user-base already there. And I think we may move more rapidly straight to the next stage of on-line services in the Web, where the distinction really does begin to break down completely, and it's just an access provision, and on-line community, and whether it's served through TCP/IP and the Web or whether it's through a direct modem or dial-up become pretty much irrelevant.

Ivan Pope: I think I'd say the answer to your question is that they want both. People want localized, language-specific content that is from their perspective, literally the [inaudible] is about, they are about the things they are interested in. But obviously people also want access to the huge worldwide content, and that's where the Web does, what the Internet will always score over the propriety services, however good they may be. And so I agree with those points there. Is there someone here? Yeah?

W: [inaudible]

[Panel]: I can comment on that, actually, for business-to-business, which primarily is the area I probably deal in more than in the consumer end of it. An example is Fidelity Investments, a big corporation over here. They have a big Web site, and you can do a lot of on-line transactional stuff, and they're all informational type things. The same thing doesn't occur in the U.K., because this is to do with a lot of the regulatory systems in different countries.

I think there is beginning now, with a lot of the multinationals, to be more of a focus of using the Web as a delivery, and more of a communication throughout the corporations worldwide. Now, how far that's gone down the line, I don't know yet; we are probably doing a little bit of research into how people are using it globally within business-to-business relationships. I presume it's underdeveloped within Europe anyway. I think within the U.S. business transactions are going on quite happily, and people think in those terms. People still don't yet think in those terms within the U.K., and I'll presume for the rest of Europe.

[Roger Green]: Another way of answering the question for the U.K. is to observe that certainly at the moment — and probably for the foreseeable future — most people who are using the Internet or heavy users of the Internet tend to be older males in the house [inaudible] with school-aged children. And that's an impression that's been borne out by research that we've done, but also research that's been done by a consumer research company called NOP of London, and more recently by Continental Research of London, who are beginning to measure

Internet use and the way they produce the industry standard numbers for the satellites and TV business.

Incidentally, you can find links to those places I've just mentioned on our Web sites, the *Internet* magazine Web site. And that's emap.com. Does that answer your question, or help to answer your question?

[Panel]: From my perspective, we deal with a lot of companies in my business, and generally we are dealing with consumer-oriented Web sites. But we are starting to see more of a recognition of business-to-business opportunities. And I think we're looking more with our clients at adding on a business-to-business element to a consumer or even to the Web site that they may already be building, and I'm sure that will lead to a recognition that there is a large opportunity there for business-to-business systems. But I think it's in its early stages.

And I think if you just look at a lot of the publishing about the Internet, both in the States and certainly in the U.K., it is consumer-oriented. I know there are a lot of tools under development that will open up the business-to-business opportunities much more; I think we're, again, we're a bit way down the curve, but the curve is upwards and I think we're going to see some very exciting developments there in the near future.

[Panel]: Yeah. I don't think there are any figures about how many people, income producers in the U.K. or, or in Europe in general have Web access. But certainly I know from looking at the access logs to our Web sites that accesses reach their peak between 9 and 5 on weekdays, by some very considerable way — which we weren't entirely expecting when we set it up. We thought evenings and weekends would be when people would dial the Internet on their dial-up accounts, and that has become the case — so much so that we've actually set up a daily sort of news update that has updates as of 1 o'clock for business people to look at during lunch times. And that's been very popular. So I don't think there's any figures, but certainly I think it's perhaps more widespread than we might know.

[Panel]: Well, there are some great products at this show. For example, [there's one] from BSDI that will make it much easier for businesses to connect their LANs to the Internet, and which indeed is something that's required here. But it's a great product from Berkeley Systems, so take a look at it.

W: [inaudible]

[Panel]: Thanks. Oh, can we go over there? Yes.

M: [inaudible]

[Panel]: I think that's one for Steve.

Steve Bowbrick: I think there's no resistance to doing commercial work and to advertising in a general sense. And I think the thing that I get, that this is less the case now, but when a client comes to visit us they're a corporate or they're an ad agency, and somebody told them you can't advertise on the Internet. And the first ten minutes of the conversation I have to convince them that it's okay to advertise on the Internet.

And I don't think there's any real consumer resistance to the commercialization or whatever, but there's a sense that you've just got to get the tone right. If you're delivering material which is classically a public service in nature, then you'll need to just get the tone of

your delivery right. I mean, I was listening to a radio, one of your public radio stations this morning in the hotel, and there was a sort of a near-hysterical ten minute fundraising section at the end of the program, at the end of each hour of programming. Which, apart from being absolutely amazing, and I wish I'd recorded it, is a very poor match culturally for European public service media. But that's not a very good answer, is it? Somebody else have a go at it.

[Panel]: Certainly in Britain advertising is a lot less intrusive with it's radio and television advertising than it is in the U.K. In the U.K. there are five radio stations which don't carry any advertising at all, and more than that there's local ones as well. There are five national ones, two national TV stations with no advertising at all. And even the two national TV stations which do carry advertising tend to only interrupt a program maybe twice in an hour, or three times in an hour, or something like that — but certainly not every few minutes, and in between the [inaudible] and all the rest of it.

It's, a very, very different model, and I think certainly in the U.K. people just aren't used to intrusive advertising. I heard the same radio program as Steve did, actually. And I was absolutely fascinated; I just listened to this fundraiser, I've never heard anything like it in my life. And it's a different way of thinking about things.

[Panel]: May I just add one maybe final point to this question? But let's think about where we are, and think about what we're talking about here. We are talking about something which is the biggest revolution in communication since the invention of [inaudible] here. There's a whole generation of consumers coming along who hate advertising. And certainly in the U.K., Steve mentioned that the people generally tend to be more cynical and they're not going to take intrusive messages.

If you want to see a fantastic explanation of this point, if you visit our country across the Atlantic, go and see somebody called Sue Little who works for [Mechanairics] in advertising in Manchester, in the north of England. They did some fascinating, dead-simple video interviews with people, customers of a cyber cafe in Bath, and in just a few minutes you'll get that things are going to have to change, even in the U.K. where it has been said that advertisers messages are generally delivered to consumers in a low-key way.

So, call Sue Little in Manchester, say I sent you, and ask to see her video, because it's very revealing about the future. You know, we're not talking about next year, but at the end of this century things are going to be a lot different, and probably in this country, too.

Go ahead. Yeah?

M: I'm just curious, what is the [inaudible] in the U.K. and throughout the rest of Europe?

Ivan Pope: Netscape.

[Panel]: Netscape, which apart from the usual reasons for Netscape, it does have much stronger multi-language supports. It supports [inaudible] characters, and gets pound signs right, and so forth. But no doubt everyone will be using the Oracle browser shortly, because that's not a legacy. Yes?

W: [inaudible]

Ivan Pope: How do we resolve the bandwidth problems in Europe in different countries?

[Panel]: Well, actually, as Stuart said earlier on that, there was 2 megabytes, or roughly, across the Atlantic. But somebody at BT tells me there's now 10 megabytes or thereabouts across the Atlantic, if you sum all of the providers back there. And Sprint and BT have both promised [inaudible], which is 34 megabytes each, across the Atlantic. And that can only be the beginning. There's all the fibers lying there on the sea floor. You know, it's very annoying that it's not being pressed into use. And I think that as an industry we must supply the pressure to get it pressed into use.

For ten years or so now, the historic rule is that everything happens nine months after it's supposed to. But, I think that you can reverse that with the Net and say that everything happens around nine months before you expected it. And so I think that we'll see the bandwidth coming sooner than we expect. But that's not, again, a very good answer, is it?

[Panel]: I think there will be a lot of more bandwidth between or across the Atlantic sea, mainly because up to now it's been the U.K. and European countries buying bandwidth into the States. But increasingly we've met [inaudible], and it will be the people buying bandwidth from the States into the U.K., which costs the same. But the way you're thinking is different. You're used to much higher bandwidth over here, and I think they will default to try to put in much, much wider pipes across the Atlantic than the U.K. companies, always trying to get the very cheapest that they can.

[Panel]: I'd like to answer from a slightly different point of view and say that if you're users are saying it's not good enough, it's not good enough; because the experience you deliver, the speed at which it's delivered is part of the experience. And so if you have people sitting, waiting for a screen to fill up, that's a bad experience.

A way around this, of course, is to have mirror sites in the continents or time zones that you need to be in. Consumers won't wait around to see something that takes ages to load, and certainly once employees or customers or partners have to re-send it, having to waste the time it might take for your organization to tell them what the prices are, or when the contract is coming or whatever...

[Panel]: Yeah, I think with mirror sites there will be a lot more of those in the next few years. And working both ways as well. It's certainly the case in just accessing our Web server internally over our company's Ethernet network; it's fine until about 1 o'clock, when America wakes up. And that's when people start to access our service from the outside, and we can't even get onto our server internally because the level of demand is so high. And so I think a lot of people are going to be looking at duplicating [inaudible], just the same way that FTP resources have had to duplicate, because there was too much demand. Web resources will have to do the same thing.

[Panel]: It's what I should have put it in — it should have been a call to action in one of my slides — [and that is to] mirror your site. There are people in Europe who will help, you know. And just to finish on that, another thing that's worth remembering is that the underlying protocols here, HTTP and IP, and they are in many cases already incorporating a provision for load sharing and automatic mirroring. [Dave Racket] and the other people at the [W30] are very focused on doing that.

As an industry we have to respond to that by providing the mirrors that then the sophisticated protocols can start to work with, and start to deliver automatically. If you connect from France you should, without asking, get the French or the European server. The protocols will support it. As an industry, we have to move to that model really soon.

W: And that's another question also. Is there a number for the Department of Commerce in those countries? See, we're trying to get a number, a number of people to [inaudible] their own [inaudible] so they can connect, so they can all interconnect each other.

Ivan Pope: It's a good idea.

[Panel]: There aren't. In the U.K. we're trying to set the Internet Developers Association, which will provide a way finding independent party people to help build Web sites in the U.K. As far as I'm aware, there's no such resources in the rest of Europe.

M: [inaudible]

[Panel]: There are similar bodies popping up everywhere, yeah.

[Panel]: I would say get on the Web and do some searches, because whenever I want to find contacts throughout Europe, I find the Web a very useful tool, and I very quickly pick up all the contacts I need. So you use the tool. And I would also say buy the publications that these guys are selling, because it provides a very, very good starting point, huge amounts of contact information. And even if it's largely the U.K., it will give you a kicking-in point, and then you can find someone in the U.K. who should be able to find someone for you throughout Europe.

[Panel]: Yeah. And there are no [inaudible] publications throughout Europe. And you know, mine are published in several different languages, and obviously their's are as well.

Ivan Pope: Right. I'll take one over there.

W: You are presenting a panel on Europe [inaudible], is there a reason for that?

Ivan Pope: Yeah, it's a historical accident. I'll pass it to Steve, he's the official speaker here.

Steve Bowbrick: I don't know, actually. I was invited to give a paper on the topic of Europe, and the slot that I was supposed to fill was nearly four hours long. I didn't [inaudible] on my own. So I've rustled up a few Europeans.

Ivan Pope: Who, I might add, happened to be here, because there was no money available to fly people in. We know we don't represent Europe in any way. We're just a rustled up group of people who do have a lot of experience between of, of the Internet.

W: One of you recommended that we look at the Europeans side, how they felt. I'd like you to be the [inaudible].

[Panel]: That's not our own.

[Panel]: There's place in Paris, they have an Internet cafe there, I think it's called Cafe [Opital], and I presume we have the URL for it. But if you look up on the [inaudible], that would be a good starting place for all.

You know, French [inaudible], I know in Spain there's been increased this year, it's just begun, and there's a lot of interest there. And Italy is doing some very interesting stuff, which I think the chap commented on earlier on.

Stuart Anderton: I couldn't tell you the name of a decent site that wasn't in English, simply because the language barrier is just as effective the other way. I mean I don't...

[Panel]: There's the Louvre in [inaudible].

[Panel]: Well, yeah. In terms of an English site that's worth watching, there's one called Anarchie which is quite amusing and changes everyday, and is very British in it's sense of humor.

[Panel]: Sort of tabloid journalism for the Web. U.K. tabloid journalism.

[Panel]: Anarchie, www.anarchie.couk.

[Panel]: The one I mentioned the Guinness was, I think it's www.icl.met/guinness.

[Panel]: I should have told them about that.

[Panel]: If only there was an easy way to register names in the U.K.

The other one to look at — I mean, he didn't say he was ashamed, but I suppose we're a bit ashamed that we're talking about the Louvre site, a very early pioneering piece of work. We're talking about English ones. There's quite a nice one which is music.com, which is an example of a trade publisher for the music industry, and he has got some good stuff up there which I personally quite like. And there's one just gone up for the London Gate Naturalists, very nicely done, a great example of using the Internet to bring together groups of people with similar interests.

[Panel]: I've plowed through the [inaudible] site on occasion, but my French is so bad... There are good sites in the U.K.. For a listing get the magazine called *Timeout*, which only incidentally we built. But also there's a good TV listing just come up in the U.K., which is, again, from the [Yearling] thing, the URL which I can't remember. What's...?

[Panel]: yearling.com, www.yearling.com. Which is the intelligent application of Web technology to a television listing, which is something that should have been done ages and ages ago, and it is good.

[Panel]: I'd like to suggest you keep an eye on the U.K. Internet Developers Association Web site, which has various addresses, but should be at www.ida.co.uk. Oh, sorry, org.uk, I always get that wrong.

[Panel]: It doesn't exist yet.

[Panel]: It probably doesn't exist yet, I'm being told here.

[Panel]: There are a number...

[Panel]: But it will be worth keeping an eye on.

[Panel]: There are a number of British-owned [inaudible], of which I thought [inaudible], just off the top of my head. Actually there's a list of all British commercial Web sites at Imperial College in London, which is www.doc.ic.ac.uk.

[Panel]: Did you get that, did you all get that?

[Panel]: I'll repeat that, it's www.doc.ac — or ic?

[Panel]: No, ic, Imperial College, so .ic.uk.

[Panel]: If I could just wrap this up, there's a good index at www.ukindex.co.uk, which is a nice, searchable index. I think that's enough sites.

[Panel]: Of course, you can always shut down European sites by searching them [inaudible], which is probably the simplest way of doing it.

Ivan Pope: Anymore questions?

W: [inaudible]

[Panel]: Self-publicity here.

[Panel]: All right. Mine's www.futurenet.co.uk.

[Panel]: And yours ?

[Panel]: Ours is www.emap, that's emap.com/internet. I've got a few copies of this magazine by chance, which we'll be happy to give free at a normal price, \$3.50.

Ivan Pope: I'll take one more question, and then, and then wrap this up. Could I take the lady in the middle, there?

W: My concern is with translation. I'd like to see simultaneous translation on the Web. I mean, could we speculate? I realize, because I speak several languages, how difficult from the spoken word to the written word in translations, which seems to be what's stopping us. But will there be anymore to the [inaudible]? I mean, that seems to be our stumbling problem, because we can't talk to one another, we're stuck in English.

[Panel]: Well, I know about a year ago there was a project — now, I'm not sure how sure it went — which the EU was undertaking, where they were trying to develop software which would actually translate from, say, Spanish to English.

M: [inaudible]

W: [inaudible]

[Panel]: Isn't there a CompuServe Forum that does machine translations through it? And also, I don't know the name of the tool, but there is a tool that works over an IP network and does

the same thing. I haven't seen it yet, but I think it's a brilliant idea, especially as a business-to-business application. The idea of offering an automatic machine translation delivered in an hour or something like that, or immediately if possible, which would give you back a crudely translated text which you could then work over — I'm sure it's an exceptionally good business-to-business application. If I could find such a tool, I'd like to roll it into a Web site.

M: I think it's, something like that [inaudible].

Ivan Pope: Excellent. A little inside information, it sounds like. Excellent. Okay, I'm going to wrap that up now, and let you get away. And thanks a lot for staying, and thank you very much to the panel.

I just want to say one more thing, to invite you again to come to London and see what's going on here. We do have Internet Worlds of our own in London. We have one very shortly in the Fall, and we have one in Spring, which is our big Internet World in London. Steve is actually the conference chair of the Internet World in London, and it's going to be an excellent conference next Spring. So if you want to come along, Internet World from Meckler, this Fall or next Spring, come and see what we're doing. Bring your stuff over, come and join in. Thanks a lot. Thanks to the panel.

INTERNET TRANSACTIONS TRANSACTION OPTIONS

MODERATOR

David Fox
Founder and CEO, KnowledgeWeb, Inc.

SPEAKERS

Cliff Utstein
Director, Commerce Products, Open Market
Michael Slade
Vice President and General Manager, Corporate Services, CheckFree Corporation
Pierre-R. Wolff
Director of Marketing, First Virtual Holdings, Inc.
Robert Hettinga
The Shipwright Development Corporation

[Host]: Ladies and Gentlemen, after Halloween night I don't want to say good morning too loudly, just in case any of you've heard enough screeches already. Of course, others of you were very good, I'm sure, and didn't go out at all, but just ate all the candy inside in the room. Of course, I didn't do either one of those bad things.

It's a pleasure for me to have the opportunity to welcome you here this morning and introduce David Fox. I won't belabor the obvious. Doing commerce on the Internet requires transactions — that's why you're here, I suspect. I will belabor the obvious in one small way, for those of you who are sitting further back in the room than the pillars are situated, I'd suggest that you have a disadvantage that will be eliminated should you choose to move to the front of the room. And indeed, there are plenty of chairs in front. But having had the opportunity to do research in the area of how people choose to sit in a congregation, if you can call it that, the more skeptical they are, the further they sit to the back; in case there's an effect of being close [that] makes you believe it or not. So, for those of you who don't believe anything about any of this, probably sitting in the back has its' advantages.

Anyway, David Fox is here with us to moderate this session. And to introduce the panelists and such. Let me say David started business in 1975 as part of a family retail operation, I gather, and in 1985 began to work and, not surprisingly successfully, because he was working with all the Adobe and Radius [people]. And then, in 1992, apparently, had the good sense to get wind of the opportunities in the Internet arena. I must say that I, myself, got wind of the Internet in 1992 and since I was an old lapsed, or have now become, at least, a lapsed academic, decided that there were plenty of opportunities to help all of us in society, educationally and otherwise, and certainly commercially, by taking advantage of the Internet.

Ladies and gentlemen, it is my pleasure to introduce David to you this morning and also to encourage you to think very carefully about what you hear today. Think about it in terms of what's real about it and what you have questions [about], because you should ask. Think about it in terms of what's important. And how does it work for you, and such. And most of all, I suggest that you think about it in terms, at least partly, about how it will make a difference for you. So, Ladies and Gentlemen, David Fox and panelists.

David Fox: Well, good morning and welcome and thank you for being here today. It's an interesting comment about being skeptical in the back of the audience. As I was walking around, sitting right at the back are people from AMEX. So, if you haven't done a lot in the Internet transaction world yet, perhaps that's true.

As I was introduced there, my original background in doing transactions was in a retail business. It was 1985 when I set up a distribution company. We represented companies such as Adobe and Radius, so I have two 'lots of experience': one in retail and one in distribution. I'm now integrating that into the Internet. So, for the next couple of hours, I and my fellow speakers, we have Michael Slade from CheckFree, Cliff Utstein from Open Market and Pierre Wolf from First Virtual as well as a wild card in here, Robert Hettinga from Boston.

I plan to introduce some ideas and make some comments and then, the speakers, those speakers, will go into more detail. Now, this isn't an easy subject to cover in just a couple of hours and of course there are more presentations today. I don't think you would expect it to be easy to cover, because the Internet will play a critical role in an extraordinary reshaping of business. The one thing I can say for sure is that this is an exciting place to be.

I first came to Boston in 1985 for the MacWorld Expo and this show certainly has the sense of excitement and urgency and doing some new and exciting things that that early show in 1985 had. I think, though, it will be a lot more successful than the Macintosh was on its' own.

The first question that I'll examine is why there are so many options for transacting business on the Internet and I'll take a brief look at standards and security and make some comments about where you might want to develop and house your site. [We will] take a look at when the actual transaction process will take place and who, within your organization, will run this — and this is really one critical question that you're going to need to answer. From there, our speakers will take you through some of the details.

Let's say at the outset, though, that there are many issues here and that there isn't a single solution for all kinds of transactions. It may seem obvious, but, depending on what you want to buy, you use different transaction systems. Buying a newspaper from a vending machine is quite different from subscribing to a magazine, or buying something out of a catalog from a merchant, that you may never have any face-to-face relationship with. Joining a professional association probably involves writing a business check rather than using a credit card. If you want to order a bottle of wine from France, you're looking at the different currencies that you may need to use. Licensing and downloading a software utilities involves other issues of immediacy. And, of course, buying a car is quite different again. Most people don't buy cars with cash, nor with credit cards.

It's interesting to look at some different payment mechanisms that we use today and I might ask for you to raise your hands if over the past week you've used cash, spent cash — all the hands up — that's not surprising. How about credit cards and debit cards? Most of the hands still there. How about checks? Less hands. How about a bank check? One hand up in the front here. Wire transfer? A couple of people have done a wire transfer. How about using a traveler's check? A couple of people use travelers' checks. Money orders? How about, who's done a secure Internet transaction in the past week? We have one, two, two? Three? Okay. How about used electronic cash in some form? *Digicash*. Okay, one at the center of the back there.

I think from that you can get the sense [that]: one, there are a whole host of different transaction methodologies. Second, that we are still in the very early days of doing transactions with the Internet. Now, these different systems of money are there for a good reason. Again, different kinds of transactions will require different kinds of payment. Paying for something from a vending machine, you expect to use a coin. Paying for time on-line, you're going to need some other kind of methodology of payment. Procurement cards, currency, frequent flyer miles, these are all kinds of issues that you'll have to think about, when you're setting up a transaction system. And, sadly, one of the things I said at the opening is that there isn't going to be one system that will do all of this for you.

One of the things you're going to need to consider, here, is the kind of business relationships that you have with your customers. If you have a spontaneous relationship, then you're not going to be expecting people to fill out some great amount of forms and go through some great process to deal with you. If you're going up to a vending machine to get a newspaper, you expect to just put the coin in and take the newspaper out and that's it. By contrast, if you're subscribing to a magazine, there's an expectation of filling out a form and answering some questions about who you are and what you're interested in.

So, again, as you set up your sites don't expect everyone to want to fill in a whole lot of details. Some people want to come there, grab some quick information and go. And, perhaps, do that anonymously, depending on just the kind of information that you're selling. Hard goods and services and digital information, again, will require different kinds of payment.

When people procure digital information I think they're going to expect, like that vending machine, I think they're going to want to put money in the slot and get the information. They're not going to want to go through a whole credit card process, forms, and a whole lot of rigmarole just to grab a page of information.

I think for many of us who are starting up a new business, we're actually at an advantage because we don't need to integrate legacy systems. This is one of the things that surprises me often — as I've done these talks and speak with people, especially people coming out of a marketing or sales part of a company — is that there is this side of the company, the legacy systems, the accounting systems, inventory systems, that need to plug into these transaction systems.

When someone orders something on-line, they expect to know that that thing — whether they're actually going to get it. And if, two days later, they haven't gotten that product, you have a very angry customer. The expectations for the on-line consumer are extremely high in the area of service. If you're starting from scratch, then you can build a whole new system that can be very tightly integrated with the Internet.

One of the issues about integrating old systems is that, and anyone who's an MIS manager here, would feel for this, is that as an MIS manager, they've got to get the network... they just kind of make it work. It's held together, somehow. And you walk along and, "Hey, we want to get on the Internet, we want to put all of our products on and make this information available to everyone in the world, isn't this great?" And they're going to be sitting back there and they're going to be looking at you with their fingers crossed, going, "No, hold back, I just have this system working and you want to let all of those people out there look at our systems? No way, Jose." So, if you have existing systems that need to be integrated, you've got some issues to think about there.

Some other quick things to think about, is what cost per transaction you can afford. If you're selling twenty cent pieces of information and there's a twenty-nine cent transaction charge each time that you do it, you've lost money. So, aggregation of payments is going to be extremely important.

Another part of this is going to be what you're prepared to risk and how much you're willing to put out there at risk for people — and that's obviously a lot easier in the information selling area than hard goods, where you've got to fix costs.

Again, how much hassle are you and your customers prepared to deal with. That early point I made about putting the coin in the slot for the newspaper and people don't expect to fill in a form every time they go to get a simple piece of information.

And lastly, I think, in this area, taking away the constraints, is actually doing some education on your customers and giving them incentives to actually deal with you on-line. And this is something I've found — as I've experimented with new forms of distribution using encrypted CD-ROM's — is that you really need to give people an incentive: give them a

product they really can't buy in any other form, to start moving them into this on-line world. If you just sit back and wait for them to come it will probably take awhile.

I'm going to touch briefly on standards and security, but again, just from an overview point rather than giving you any real detail. Amir Herzberg, from IBM, is here after lunch and they have an excellent security system. And there are many around the show, and many other sessions here.

I think [these are] a couple of important points. One is that there are already a lot of standards. Who knows what all these acronyms mean? Three, four, five, six, yeah. Well, that's pretty much what it's like out there. I think for a lot of you there's probably not a lot of reasons to know about them. I think that there are other people who will do the learning on these systems who will be able to set up the transaction processing systems that take care of these different standards. If you want to have a little bit of [a] late night, get to sleep reading, take a look at any of these documents. The specifications and implementations for any of these. It's interesting reading.

Beyond those standards there are other systems, such as Cybercash, CheckFree, Digicash, and [then] there are the standard bodies that are trying to work to bring these together.

The thing I'd like to say about standards, is that they are critical to making this whole Internet transaction business happen. Because if I have to go, if I want to go to "Molex" and I've got to use some special browser for it, and some special password, then, there's going to be about three or four places that I'm going to shop at and that's about it. Because I'm going to forget how many passwords — how many people here have trouble with their passwords already? Yes. Now, we've got some hands raised, great. This is a real issue that the service providers need to get together on, because we've got this great dangling chain of keys that we're carrying around with us, except it's in our heads, and we tend to forget what these key numbers are. This is a really critical issue.

Essentially, standards precede widespread adoption. That's just a simple fact. If I can't take this automatic teller machine card and use it in a range of machines, or take this credit card into a range of merchants, it's not going to get widespread acceptance.

And whatever standards come along, need to address multiple groups. They need to address what consumers want to use, what businesses are prepared to deal with, and also regulations. And this is one area, the regulations area, that I think is lacking, [and] has fallen behind the pace of change. That's probably stating the obvious. A lot of this work can't take place without a context of rules and regulations that cover it.

It's an interesting question about what standard will win. And I certainly won't stand here and predict what that will be. I think we've seen this happen time and time again in the consumer electronics world where, we had eight tracks, moved to cassette, and then there's this other thing called DAT. Well, is DAT better than cassette? Yes, it is, but has it had widespread acceptance? No. It has got acceptance in a specialized market area and that is the professional recording area. So, one standard that may do well like cassettes in the consumer marketplace, may find a different standard taking hold in the business marketplace. And again, my point where there's no one solution that's going to cover this whole gamut of Internet transactions.

You see the same thing happen with the beta and VHS wars, where VHS won out. And yet, there's this other standard that came up, called Video8, because it offered something that gave you a long tape, for low cost, in a very portable environment and helped make small cameras. Laserdiscs, I think, are giving way to CD-ROMs, and [then] you have other standards, like DCC and mini-disc, that don't seem to have gotten anywhere. They've gone past the consumer's interest and they don't offer enough beyond standard audio CDs.

So, standards are something that you're going to have to watch very closely, they're something that you need to abide by, because if you're off making 8-track tapes, then you're going to find a pretty small market.

Security is another area I'll touch on briefly. I'll be asking you to raise your hands again, but how many people here use PGP or one of the other security products? A few paranoid people here, but justifiably. Now, the thing is you have twenty hands or so out of 150 or so people. Anything that involves high levels of security, cryptography, and so on, don't expect these to become standards overnight. Here we are a fairly leading edge group of people here, and four out of five of us aren't using any kind of cryptography security at the moment. Then, don't expect the audience at large to go through much hassle in doing that either.

Whatever you do in the security area is going to involve trade-offs. It's going to involve trade-offs between ease of use, on the one hand, and effectiveness, on the other. The ultimate way for security, have keys that change every day, hardware-based security at both ends — these things are impractical for most people to employ. One thing I would say to watch for is the rise in smart cards, the stored value cards. I think we'll see those playing a critical role. And if we have a whole lot of software break-ins, then I think this business won't take off until you have something like a stored value card where you've got this piece of hardware that is a much higher guarantee of security.

The essence here is the tougher you make it on criminals, and vandals, the tougher it's going to be for you and your customers. The more encryption you use, the more computing power you'll need to decrypt the stuff and the more computing power that's needed to decrypt at the consumer end as well. There is a real benefit, though, when we actually make the standards and make the security work on the Internet.

For those not familiar, this concept of card-not-present sale is an important one. In mail-ordering, and people who do business through the Net are classed under mail order, there is an added [cost], an extra percentage that you pay because you don't actually have the consumer's credit card in your hand. And that might be, [say], .2 % or .5%. It's something extra that you, and in turn, the consumer are paying, for that card not actually being present. I think when we get an end-to-end security worked out here, you'll be able to achieve a better discount rate, [because].2% on a hundred million dollars in transactions — we're talking some real money there.

A couple of points about where to develop your site. A few years ago, there were really only two options. They were to do it all yourself, or to go with a commercial on-line service, and we're finding some in-between points now, companies like Open Market, First Virtual, with their info house, offering in-between points that give some of the control and flexibility that you'd have as a do-it-yourselfer, without some of the risks. Let's take a look at that.

Control, flexibility, time and market is what you may gain by doing this work by yourself. And, of course, because you're not paying out to anyone else, you'll have lower costs, if your volumes are high enough. If you're going to do a couple hundred thousand dollars in transactions, the hundred thousand dollars you spent in setting up the system may be a complete waste of money. You may be better off paying 20% to Microsoft Network than trying to set up your own system. I think there's a fair downside to trying to start from scratch and do all this work yourself. That control, flexibility, time and market can actually flip over on you. And I've seen this time and time again out there, where the control actually gets out of control, you have inflexible systems that take months to get to market.

There are plenty of up front costs in building a system. You could easily spend \$70,000 or \$80,000 to run your own system. Between the cost of a server, a line, and in fact, multiple lines, because it may be fine if you're running a bit of, doing some marketing on-line, that your systems isn't available here and there. But if you're doing transactions on-line and people are

coming there to do a transaction and it drops them out halfway, you're going to have a lot of customer service issues to start dealing with, and that's seven by 24. Seven days a week, 24-hour availability is going to be critical in making these Internet-based transactions work.

You know what it's like on the Net. Whose Internet connection works all the time? Right. How often does an ATM not work? Not very often. If you walk up there and every third time you used the ATM, the thing didn't work, well, you'd probably soon give up on the thing. You know, we are dealing with computers here, and reliability isn't one of the great things about computers.

If you're doing this yourself, you also need to understand the complexity, the security and the technical requirements. If you're a propeller head, that may be of great interest, although I might recommend to you that you might be better off billing your time out to someone, [rather] than trying to build your own system. The key thing here, I think, is that there is a real move away from core competencies if you try to take on too much of the work.

Internet service providers may offer an alternative. You certainly have got some expertise there, the focus though — and you really need to look at this if you want to partner with an Internet service provider — is on pipes and switches, rather than on whole end-to-end transaction processes [that] the guy in the Open Market goes through. As we go through the Open Market presentation, if you're not familiar with this end-to-end transaction, I think you'll understand what I mean there, after his presentation. And again, is this really their business to be in.

And on [the] Internet, some kind of aggregation service may be another way to go. There's certainly going to be less up-front cost, much faster time in market, [because] you're using the experience of people who've been there and they've done it before, and there's the potential that they can provide some early traffic to you. On the other hand, you do lose some flexibility, you are sharing information out there, and who knows, you might have a competitor sitting right next door to you. You may have some branding issues.

I think the other issue here is, of course, finding the right partner. And isn't this what business is all about? What makes the difference between good business and bad business, are the people that you're working with. And it's really hard to work out today who's going to be a good mole partner and who isn't. Who knows, you might end up with one of those landlords, like in real estate, that just want to gouge you. It's probably easy to pick up and move shop though, that's the one asset you've got. And of course, you'll have a revenue sharing... some kind of revenue sharing split with them and you just need to do the numbers on that. If you're going to do a couple hundred thousand dollars worth of business, right now, I'd say to most people: unless you're really interested in the technology, just forget about trying to set this up by yourself. Working with a [mole] or some kind of aggregator is going to be a much better way to go.

One of your few options awhile ago was a commercial on-line service. One of the things they bring is a big base of customers and they already have your credit card number. So, if there's something about transferring credit card numbers around, it doesn't matter because they've done it, they've done it through a secure link — the link when you first registered. And they've got your card there and they make the transaction business really easy.

Again, you've got a big revenue sharing thing, [although] it's starting to get squeezed down, but, we're putting our service up on Microsoft Network and they want 20% or 30% of the take. Which is better than the 80% that CompuServe, AOL, and Prodigy used to take. So, 20 versus 80? They certainly lack flexibility, though you're going to have to fit in with their structure — just try and do something interesting on Microsoft Network now. Good luck. Maybe next year.

Differentiation might be difficult, maybe less so with the new systems, but with the old systems, you had their box to fit in and [to] try to differentiate and get your brand across is very difficult. And this earlier point I made about your transaction system: if you're shipping hard goods, that may be a real bear to try and hook your transaction system up with theirs. So, take a good look at these things.

An interesting point, did someone mention the government here? They were certainly talking to someone from the military up here before. These issues of sales tax, contract law, rules and regulations — these don't go away in cyberspace, these exist. There is a body of work that a colleague of mine, Benjamin Rider has done called, *The Law of Electronic Commerce*. Don't drop it on your foot, it might hurt. There's a handout on this at the back, if you're interested, or have people in your organization who might be interested.

A lot of the rules and regulations that you need to understand have been developed for EDI and — Electronic Document Interchange — it could be a place to look. And, of course, this global market is fantastic, but there will be some global issues for some of you. Not for all of you, but there will be some global selling issues about whether you can sell into certain markets, and what you can say and what kind of visuals you can use — you don't want to end up going for a holiday in Iran one day and being arrested for the skimpily clad woman you had displaying your merchandise. More bizarre things could happen out there. And they probably know who you are and may be tracking you.

The other part here, I'll just touch on, having been a distributor in another country, and worked with the issues of where we made out money, was on the up-lift: how much over the U.S. price we could sell at. In fact, a lot of the publishers we dealt with always wanted to have a higher price they charged international distributors. Well, what's going to happen to your customers out there, to your distributors, and your resellers out there, when your customers in other parts of the world can see the prices that you're selling for in America, and see the services that you're offering here. It's not a government thing, but it's something that you need to think about in the global market.

There are three basic times that the transaction can take place. It can take place off-line, which is really the brochure phase that most of the Internet is in at the moment: this is where you offer the product for sale, people may fill in a form on-line, but more likely they're calling in to an 800 number.

Most of the on-line work that's getting done today is batch-oriented: the information comes in somewhere and, in most systems that I've looked at, it actually gets re-keyed somewhere else into an order processing system. The kind of system we really want to get to, though, is an on-line, real-time system for most users, where the Internet is transparently hooked into your in-house system. There may be a mediator there between you and the banks, for clearing a credit card — Michael Slade will talk more about some of these issues. But, there are three distinct ways to go with an off-line transaction when someone is calling in. Obviously [it is] not a full Internet transaction. It's really just a brochure on-line. You really need to be careful, in this batch-oriented world, especially if the people that are batching it may be slower than your ability to get out there to customers. People on-line, again, have real expectations for real-time information and real-time delivery of products.

One of my closing points here is, who should look after this from within your company, and I'm seeing all sorts of different people taking charge. I think that essentially the direction needs to come down from the CEO, the executive in the company. The only problem is, and with apologies to some of you here in the audience who are bringing yourself up to speed, is that most of these people are clueless when it comes to technology. And there really is a gap between what they really need to know and — any of you who are having that experience already of trying to explain to a CEO or your executive what the Internet is about and what

doing an Internet transaction is about when they've never even seen the Net, you know, it's a lot of hand-waving. You really need to encourage these people to get on-line and start using it.

Most people are creating some kind of new group within the company. But then again, this group, if there isn't a really close connection to that executive, you're going to have some real problems, because it involves sales, it involves marketing, it involves the distribution. You can make a great site and do great transactions, but then if order processing takes three days to get this thing out the door, what you're dealing with is an awful lot of unhappy customers.

I've set up a set of pointers — you may like to take a look at these. [They are at] www.payweb.com/d-commerce. These are pointers to about 150 sites where you can get a lot more information. I've done this rather than giving a printed handout today, because this information changes so quickly. One of the other sources is... there finally are a couple of books coming out. In fact, I've got two copies here of a book called *Digital Cash*. So, when we go to the panel session about midday, I'll get a couple of people to come around and collect some business cards from you and we'll do a draw for these two copies of *Digital Cash*. It's a new book by Peter Weiner, it's on AP Professional Press and it actually comes with some First Virtual software included.

There is another new book, I was just at an electronic commerce conference in Austin, there's a new book coming out called *Frontiers of Electronic Commerce*. This is another one you wouldn't want to drop on your toe, it's 848 pages, it is written by two gentlemen named Rudy Calcutta and Andrew Winston, the book is \$45.25 and it's not available on-line. How amazing. And surprising. But it is on Addison-Wesley. There's bound to be a whole stream of others. I think there's one that's been done recently by one of the people involved with CyberCash. And this reading really will be essential if you want to get a broad overview.

And with that, I'd like to turn to our four speakers. Our first speaker is Cliff Utstein, from Open Market. I saw his presentation yesterday on the Open Market system and I think this is a great system. I think they're on a real winner here. They've brought together... they've taken it from two levels: they've brought together a lot of the separate components that you used to have to string together yourself and, on the other hand, they've given you a lot of the benefits of a commercial on-line service. The back end transaction processing — they've broken that away from the front end. You've got total control over how your site looks, and they control the back end. I really think they've got an interesting site.

Following is Michael Slade from CheckFree. We'll talk about their system, they made some announcements yesterday. And then we'll have Pierre Wolff from First Virtual, whose system has been operating successfully for one year on the Internet, which few people can say — I don't think anyone else can say, and he's got some interesting things to say as well. At the conclusion of their formal presentations, I'll introduce Robert Hettinga, who's a local in Boston, as I said, the wild card in this bunch. And we'll have half an hour or so for a panel discussion and more questions.

If you've got a couple of questions for the presenters in-between as they change equipment, we'll take one or two questions, but I'd like to keep this kind of moving forward and then open this up for a panel discussion at the end. So, unless there's a burning question for me, that someone really has to ask now, I'll hand it on to Cliff and go through the other speakers, and we'll all get back together at the end of this. Take it away.

Cliff Utstein: Thanks David. As David said, I'm Cliff Utstein from Open Market and I'm going to spend about twenty minutes this morning talking about Open Market's commerce architecture. If you would like a copy of the presentation, the best way to get it quickly is drop me an e-mail — and I've got my e-mail out there, utstein@openmarket.com. I can either snail mail it or e-mail it to you in *Power Point* or *PostScript*, just let me know what you'd like.

I'm going to focus this morning on our commerce solution, as I said. And our commerce solution is a set of software products. What I'd like to do, actually, is start by telling you just a little about Open Market, and just spend a moment or two. Open Market has been around since April of 1994, which makes us one of the oldest Internet-focused companies. We're based right here in Cambridge, Massachusetts, and we're up to about 165 employees, but that number seems to be changing more rapidly than my presentation can be updated. We've got about five to ten people a week coming on right now. We just rented four floors in the old Carter, Inc. building right on Memorial Drive and we're growing very rapidly.

We are privately financed. As you see there, major publishers are the primary financial backing of Open Market and also, as you're probably aware, much of the backing of the Internet today. Time-Warner's *Pathfinder* site is a great example of some of the work that we've done, Advance Publication's Conde Nast with their Traveler's site, the Conde Nast Traveler's site in the Chicago Tribune.

By way of background, I would like to just put up there, some of our customers, and some of our partners. Some of the ones to point out there from a commerce perspective, Bank One, is one of the top ten banks, we've done an EDI solution for Bank One. Where libraries today can buy publications and periodicals on-line right from the manufacturers and publishers of these. It's a solution that, when taken to EDI on the Internet, cut 80% of the cost out of the purchasing and the distribution cost here. It's truly revolutionary, the message that Bank One is getting from their customers, that this is not cutting 5% out of the distribution and ordering costs here, this is 80%, [this is] big news.

First Union's another partner of ours. First Union is looking to bring up 35,000 merchants in the next year in their community environment. Anyone from the North Carolina area that wanted to go to a Durham Bull baseball game this past year could have actually bought their tickets on-line, using Open Market's commerce architecture. Those are some of the highly visible ones.

We have relationships with American Express, with "Lydol," with CheckFree, as well. We also made an announcement, just this week, with IBM. IBM's going to be running some of our back-office software and that will be clear. What that means is that I go through our architecture, with a front-office, back-office scheme. FTP's another partner of ours that we recently announced, CyberCash, as well.

So, just to list a few and to give you a flavor of where Open Market fits in here. In our work with these partners, in developing solutions, we've actually been through several iterations since April 1994, as to what Open Market, as a company, is going to do. And, unfortunately, that comes back to haunt us every once in awhile. People say, "What does Open Market do?" And let me take you through some of that.

We started out consulting for *Time* and some of the other publishers and developing solutions for them. We then transitioned into a service area, we thought we were going to be the biggest marketplace and the biggest mall on the Web and we've since moved to an environment where we are a software company. And we are developing software for businesses, for malls, for service providers, for their solutions for electronic commerce and enterprise solutions on the Web.

Through all of this experience that we've gained, thinking we were going to do it ourselves, working with our partners on a consulting basis, we've been through a lot of the obstacles that everyone's facing now, doing it for themselves for the first time. And what we're proposing here are these seven requirements for highly effective Internet commerce.

Let me take you through each of them briefly. These are what we believe the highest level... most important areas that you should be thinking about when you think about running your business on the Web. Number one, I'll bet everybody's thought about security. How many

people have thought about security? This is the big one, how am I going to do it. How many people are concerned about sending their credit card information over the Web? Whether they're using STT or SEPP or anything? Okay? About a third? Security is a big issue and having security commensurate with the information that you're trying to protect is very important. One note here, is that it does take a different amount of security to protect a credit card where the liability for the consumer is \$50. Obviously, the liability for Visa or Mastercard is a lot more if they were to get out in the masses. However, from a credit card standpoint, a credit card is really not a secure number, every waitress in this town got 15 of them last night, so they're not that secure. There are things, obviously, that are much more secure than a credit card, like, if you're a bank, the ability to move funds around as a customer, so security commensurate with what you're protecting is really the message here.

Number two, the ability to focus on generating compelling content. Using the right HTML authoring tools, setting up the relationships with third parties, being able [to utilize] HTML links on the Web, being able to customize the site on a personalized basis. Knowing that if a customer comes in and buys a black sweater and then black shoes and black socks, the next person who comes in to buy a black sweater... you'll probably want to show them the black shoes and black socks somewhere on that page, because you've learned something about buying habits of your customers when they've bought something. Setting it up so that, if you've got a customer in one that subscribes to your service, you're going to show them something different than one who hasn't, maybe they get special offers, special pricing, etc.

Number three is the area that most people focus on when they think about electronic commerce, and that is the on-line order taking and payment processing. Obviously a very important component here, and we've got some experts who will speak about this after myself. The ability to fulfill soft and hard goods — soft goods, of course, in light of this new medium. The ability to, at three in the morning, go in and buy a report and have it on your desk instantly, is the compelling area here. The ability, as a software company, to be able to sell your software and have that downloaded instantly by the customer. From a hard goods perspective as well, as David was saying, to link up your distribution mechanism — to give customers the option that, if they want Federal Express, that they'll have it the next day. And taking care of the hard goods delivery there.

Customer service is another real big area that people setting up their business tend to sweep under the rug when they start. And this is essentially a very expensive area because, when your customer runs into a problem on the Internet, as David was saying, the Internet is not always there, the phone line goes down in the middle of their downloading of the information they just bought, they're not sure whether their transaction has actually gone through, what do they do? A natural thing to do is to go and pick up the phone, because they want to talk to somebody. What we're suggesting is [to] provide them with a solution on-line — where they don't have to do that, where they can go and check on the records, on the logs of everything they've done and be able to reacquire goods that they were in the process of acquiring, or even reacquire goods if their hard disk were to crash and they were to lose their goods, through no fault of any system.

Every phone call — Visa and Mastercard estimate — to them for some type of dispute or question runs between \$50 and \$75 apiece. And, typically, what they're doing and what the business is doing, is actually acting as a human modem, downloading the information via telephone that the customer could be downloading [from the] system, etc. With that, by way of background, as areas to think about, what I'd like to do is transition into our architecture and what our products are based on essentially.

This is the Open Market commerce architecture, where we separated into three phases, here. You've got the buyer using their browser, any browser out on the Web, and as you

know, there are many, many browsers. In fact, coming into the *Pathfinder* site we're actually doing some checking right now, because we're doing the authentication for the *Pathfinder* site, and on a daily basis, there are approximately 180 browsers that come into the *Pathfinder* site. And those are different releases from 1.0 to 1.1 to 1.2, etc. And, of course, all of the different on-line services have their own browsers and all the different browser manufacturers and the browsers that are being built into applications. So, being browser independent is really a key message here, and that's just the same as saying in the concrete world that you'll accept anyone who walks into your store.

From the front office perspective, as we move there, this is what we're calling your business, your traditional business, this is what you're doing today, converting your business, your front office into the Web. And, if you're selling information, it's a dynamic representation of that information for the Web. If you're selling hard goods, it's compelling representations of those hard goods, maybe with contests or other things. This is what you do best in your front office. This is the merchant and the business.

The back-office, in this scheme, is actually a service provider. This back-office is, if I were going to draw the example to the concrete world, if you set up your business today and you're 15 people, the last thing you want to worry about, when you're worried about your line of business, is payroll, or accounting or your legal services. These are all functions that you want to off-load, and what we're proposing is that you can off-load all of these functions. And I'll go through, from a Web perspective, what that means to a service provider, a third party, and let you focus on your HTML content, your Web server, your site, your front office concerns.

This architecture actually is very close to — how many people have ever shopped at Toys 'R' Us? Okay, good. So, this example is going to work for most of us. You go into Toys 'R' Us and you find what you want, or you work with a salesperson within Toys 'R' Us, and you find this product that you want to buy and there's this ticket on the side of the product and you take it off the rack. And that ticket uniquely describes the item that you're buying. Everything from the manufacturer, to the price, to... if the offer is a special that week, they've got tickets just for that week, uniquely describing that product. Then, you take that ticket and that's the front office, that's the shopping area, over to the cashier and that cashier authenticates you, takes your form of payment, asks you if you want to pay by cash or check or credit card and that's the back-office, now.

You've actually made a transition, in this model, from your ticket, to going for payment, and adding in the sales tax and the shipping charge, if there is one, probably not at Toys 'R' Us, but all of the back-office processing, and what you end up with, there, is a receipt. And you take that receipt back, in this example to a front office, but, you take that receipt to the shipping department and they look at that receipt and they, in fact, authenticate that that receipt is valid and give you the item.

Same model here. You go into the front office to buy a report, some software, or a hard good, and you find the product that you want in that store that you've generated and there's a digital offer there. And that digital offer is actually a redirect to a back-office. And it can be any number of back-offices. IBM has announced that they're running one, Open Market's running one and you'll see additional back-offices on the Web this year. You go to that back-office, now as a consumer, and you buy the item. And the sales tax is added in, and the shipping charges and everything else is added in, and you get a receipt in that back-office, and you are a redirect again — this time back to the front office to get the item.

So, that's how this model works. You focus on the front office. You focus on your business, you don't worry about what happens after they leave your site, except that they're going to come back with the item already paid for and their receipt. So, how do you set this up is usually the next question. It's actually quite simple. You create your HTML for your front

office using any HTML authoring tool, we actually have one called *Store Builder*. [It is] not required that you use that. You can take your existing content and in there, you've got your HTML. You put it on your server, any Web server, it doesn't matter, we do have Web servers, we'll talk about them. Any Web server, and then you commerce enable it. And the commerce enabling is this act of building in the digital offers into your front office and being able to accept digital receipts. And then you're up and running in business on the Web.

From a standpoint of an overview here, you focus on the front office, you let the transaction service provider focus on the back-office and you can go in and commerce enable your site. How many people already have their sites up and running? Okay. About half. If you've got your sites up and running, you're going to commerce enable it, if you don't have your sites up and running, you can start from scratch and start with the idea in mind of commerce enabling your site, as well.

You get to incorporate back-office features as they come on-line without any additional work. The same way that a front office in the Toys 'R' Us model [works], the playpen doesn't care whether you're buying it with cash, buying it with a Visa, buying it with First Virtual or CheckFree's wallet. It doesn't make any difference, you incorporate those things transparently into your store. So, as Visa's STT or Mastercard's SEPP or one of the other payment protocols come on-line, they are all developed on the back-office software and you, as a business, don't worry about any of those things. You can accept all the payment mechanisms that are available on the Web, from the back-office perspective.

It utilizes widely deployed standards, in fact, you can go in today, into Lexis/Nexis and try this out right now: buy reports from Lexis/Nexis one at a time, pay per report, where you're going to go from the Lexis/Nexis site back to the back-office to pay for it, get your digital receipt, go back to the Lexis/Nexis front office site and have it downloaded. It's open and it's standard spaced. We use any Web server, any authoring tools, any browser, we're going to be publishing the specifications to the digital offers and digital receipts this month.

The first product availability will also be [out] this month. Let me take you through some of the components here. We've got a product coming out this month called *Merchant's Solution*, which the green components are actually the parts of. Where there's a Web server — we talked about that in the front office — we're providing the Open Market Secure Web Server which supports SHL and SHTTP, and I can get you all the information you want on that off-line.

We're providing an HTML authoring tool called *Store Builder*, which allows you to very quickly, in a Windows environment, set up a commerce enabled site — complete with departments and products and all the links that you want. As I mentioned before, you'll want to commerce enable that — and that's what Transaction Link does. And that's really at the core of this architecture, from the front office or the business standpoint. Running this transaction link piece, and that runs the CGI script on any Web server. And then from a reporting standpoint, you want to know what in your store is working — why isn't anyone buying those purple socks? Are they on a page that nobody's accessing or are they getting there and \$22 is just too much for purple socks? So, you want to figure those things out. And Web Reporter goes in and orders the log files from any server and provides you with reports customized and based on your requirements.

Finally, from the back-office perspective: linking into the transaction service provider. Let me show you what you get when you do that. First, customer service. This is one of the areas that most people aren't thinking about, and again, we provide a log file so you can go in [and] see everything that you've done — all of your history is on-line, and all of your digital receipts are on-line, as well. Those digital receipts, remember, are pointers to the information that you were buying. So, you've lost a report or, like me, you were shopping in the middle of

the night and your Visa bill comes 45 days later and you can't remember that you were doing that. You go into your Smart Statement, and you click on your digital receipt and there it is again, the report that you were buying, the one that you can't remember. [So you don't have to make any phone calls — customer service is] all automated on-line.

Of course, the order taking and credit card authorization and settlement's all on-line. The sales tax piece is a very big piece. As I talk to people that, up until now, really haven't had a solution like this in businesses, where they've spent 50, 75, a 100, to a \$150,000 on the development of their commerce enabled site. They talk about things like, how they're handling sales tax and multiple geographies and writing the CGI scripts to do that.

None of that is a concern in this model because that is all handled in the back-office. You go in when you register and specify what locales you have to charge sales tax in, and it's automatically calculated for you. And that's a product that we're getting from a third party, that's going to be updated regularly because, as you know, the sales tax code seems to be changing every few weeks.

The back-office is where the digital receipt is generated, where the shipping fees are computed. And as a business you go in and register how you want to handle shipping, how many options you want to provide people. And the customer specifies whether they want to use FedEx, the post office, or whatever, and the charge is automatically calculated in their purchase order.

The next point, based on the number of hands that went up, I think is going to hit home. We provide account-based purchases with no Internet transmission of credit card. So, you come in one time, you set up your account (and you can do that with your secure browser on-line). You can do that by telephone or by fax: you set up your account once, you've registered with the back-office, and now any merchant, in any store that's tied into that back-office... you'll be able to buy from without resending your credit card over the Web.

We do support walk-in purchases, if you don't want to set up an account, so you can walk in using your credit card or using another payment mechanism like a First Virtual or a CheckFree wallet, or whatever, right on line, and we also support customer shopping carts. So, when you go to the back-office, the first question you're asked is: "Do you want to buy it now, or do you want to add it to your shopping cart?" And then you proceed from there.

I think that gives you a good summary of the architecture and we're actually going to be doing demos in the booth, as to how to buy things. And we're going to be selling pens on-line for anyone who wants to come by and buy a pen using our credit card and have it shipped to them and see what it's all about.

Let me leave you with an example of how this architecture works from an Internet standpoint. [You can have] multiple merchants on the Internet, all linking into the same transaction service, for payment authorization, processing, sales tax, shipping charges, Smart Statements, etc. And, as the businesses grows, you see there, multiple size merchants all linking in over the Internet. From a small business on the left, growing into a large business, with multiple content sites, in varied geographies, to a very large business that actually decides, hey, "I don't want to go off-line for my service, I want to take that in-house and run that myself, as well," that's Okay too, because the architecture truly scales here.

On the thought of doing it yourself, from a contrast standpoint, when you do it yourself, what you're getting is one instance on one server for this and your business grows. You can go and buy a bigger server, and run it on a bigger server, but now you need to set up more servers, and how are you going to do it? Are you going to set it all up again, replicate the system? It becomes very complex and very costly to do that. In this model you're just focusing on your content, so that's not a concern. And, as your business grows large enough, if you want

to take in the back-office — your business is big enough to do your own payroll, great. You'll do your own payroll now in the concrete world example. Same thing here.

Let me wrap it up with a closing thought from the economists this summer, talking about the magnitude of the Internet from a historical perspective on society and on mankind. Number one being the wheel as far as the influence it's had on us. Number two being the printing press. And right up there, number three, is the Internet. This is not something to be ignored, this is not something to do a six month study on or a one year study to figure out what you want to do and let your competition beat you to the punch.

And you know it's harder, the bigger you are as a business the harder this is to do. In any revolution, the larger players are often not standing after the revolution is over, because they weren't able to change as quickly. There are new players standing at the end. And that's really the message here, from a mainstream non-technical publication, like *The Economist*.

So, to wrap it up, open-standards-based technology, integrating with solutions — like you're going to hear about next — a secure business environment allowing you to focus on the front office, [and] off-load the back-office services. *Merchant's Solution* was just announced on October 16, and it's going to be shipping this month. I can say that now that we're in November and I would encourage you, if this looks like the type of architecture that might work for your business, to come by booth number 456 and we can tell you more about it. Thanks.

Michael Slade: Good morning. As David said, my name is Michael Slade and bear with us, while we arrange the technology. Yes, a question.

M: [inaudible]

David Fox: So, the question is: "How are people going to register on-line now and have a transparent way of using this?"

Cliff Utstein: Initially, what we're doing, is: the transaction systems are tying into the Visa and Mastercard network for the transactions. So once you've got your Visa card, we actually tie right in through the transaction management system. Or if you, as a business, were to set up your own transaction management system, you would tie-in through your payment processor like CheckFree right into the Visa network.

M: [inaudible]

Cliff Utstein: Got it. The question is: "Would you, as a customer, have to register with each of the back-offices?" And the answer is initially for the rest of this year, yes — the transaction management systems are not linked. However, over the longer term, the idea is to link the transaction management systems. A question in the back?

M: [inaudible]

Cliff Utstein: The question is: "What happens if the link is down, for you as a business, to your back-office?" And the answer is that you will not be able to process. Obviously, it's the same answer if you were to set it up in a different architecture and you were to set it up locally and your link was down to processing. So, if your link is down, you're not going to be able to process either way.

M: [inaudible]

Cliff Utstein: There is the potential for more links, although there's also the potential for less links, depending on how you're processing. If you were to set up all the scripts to do all the credit card processing, and you were going to do a dial out phone line into a third party and then get into a centralized clearing, there actually could be more links that way. So, it's unclear, but you're right. I think that, as David outlined at the beginning, I think we need to make sure the Internet is there 100% of the time for this stuff to truly work.

One last question?

M: [inaudible]

Cliff Utstein: How are the screens at Open Market branded from a back-office perspective? The front office screens are branded in the front office however you like. The back-office screens are branded from the transaction service provider. Today, Open Market's running a transaction market service and they are brand new with Open Market. The idea here is that, if you are a business and a customer has come to your business from somewhere on the Web, from some random hypertext link, and doesn't know you, do they actually want to send you the credit card or, if they're on the Web and there's a trusted back-office, like IBM, are they more comfortable sending IBM the credit card? You're right, the screens, and how that transition happens, has to be very smooth, but there's a whole trust element here with the back-office being run by an IBM or, potentially, very large transaction providers.

Recurring payments?

M: Don't worry I do those.

Cliff Utstein: I'm not sure what your question is around recurring payments. From the back-office perspective, how the business is built from the back-office? Or to sell? So, you want to sell a monthly subscription utilizing the back-office. That's not something that's automated right now in this architecture in the back-office, it's something that you would automate in the front office, today. And a customer could actually go in and try to get it, on the 32nd day, and be directed to a screen that takes them back to the back-office for payment on the 32nd day.

Michael Slade: Hopefully, I'll address those two and a few others, but I encourage you to write those down, because those are the types of questions that we find people in the marketplace are trying to get answers to, because, as you have seen earlier, I'm finding a difference at this Internet World Conference than the previous two. It's obvious people are ready to do things. And these questions are indicative of months, if not a year, of hard work trying to make this happen. So, I encourage you to write those questions down and challenge, not only us, but others here, at the conference, to provide you answers, that's what we're here for.

Again, I'm Michael Slade with CheckFree, and I don't see Bill Washburn from Mecklermedia around, but I'm amazed and we should congratulate Meckler, because Sunday, Monday and Tuesday we had the best weather Boston could offer and that was the sizzle in the steak — the front end if you will. Today, we're talking about the down and dirty, back-office activities and look at the weather outside! They've arranged good weather when it should be, and now we're in here talking about the difficult things.

If you're looking for technology answers from me, I'm afraid you'll be disappointed, I'm not a technician. As my cohorts up here saw me struggle to get my presentation together, that's not what I'm here to do. I'm here to talk about electronic commerce and how to enable

merchants, retailers, etc. to expand their business and move into that 24 x 7 — take advantage of this sphere of boundless opportunity and turn it into real world hard, cold cash.

My role at CheckFree is to adopt our expertise in technology, into the standard, traditional business models. What we're finding, and I'll get into this a little bit later, is that people who intend to sell goods across the Internet [who] have already been in business, in a brick and mortar setting, cannot afford to change the way they do business, as well as deliver a new distribution system. So, what our role is in this confusing world is to help marry traditional — I like to call it the old dog... and teach it new tricks. And that's what we do.

CheckFree has been in business since 1981, we're based in Columbus, Ohio, and have been [in] the transaction process for remote transactions since our beginning.

David mentioned earlier the on-line service providers already have your credit card number. Well, what they do with it is send it to me to get it processed. If you are a CompuServe user for example, the guy standing here in front of you is the one that's processing those transactions for your monthly subscription fee.

In 1995, CheckFree will process a little over \$9 billion in remote transactions between consumers, companies and financial institutions, represent[ing] a little over 60 million transactions. We think that in any commerce model, there are three parties: the buyer, the seller and the financial institution that mediates the movement of the money between the buyer and the seller. CheckFree is a service provider, we are not a bank, although we are capable of many of the transaction processing operations of a bank, we are not regulated as a financial institution.

In the consumer world, we have three products that have been around. *Bill Delivery*, which is the last one on the screen, was just announced last week. That is the service that allows the consumer to receive their monthly bills from their billets. The pilot began last month, and it involved Southwest and Bell telephone as well as three utilities in South and Central New Jersey.

The CheckFree payment service is the leading electronic bill paying service today, allowing consumers to use PC's and touch-tone phones to pay their monthly bills. At the Internet conference, here, we are focusing our efforts on the CheckFree wallet. Which is a secure purchasing facility across an open network. In the business sector, we offer a variety of goods and services as well. This is a business unit that I am responsible for, and, again, our specialty, here, is in moving money between a buyer and a seller, whether the buyer is a consumer or another merchant.

In [the] financial services arena, we provide wholesale services, if you will, to banks and other financial service companies — which gets to the issue of branding, which I'll talk about in a minute. Branding is a very important issue right now, even more so to the consumer. We don't have a lot of time to figure out a lot of things, so we tend to trust brands we're familiar with. And I'll go into that in just a moment — right now, as a matter of fact.

In the roughly 15 years that we've been doing business, we've built a database of knowledge and information that tells us some things — we've learned some lessons the easy way and we've learned some lessons the hard way. First of all, what we have found from consumers is they understand clear value propositions. We as consumers don't understand complex messages, that's why TV commercials are becoming five seconds rather than a minute. We just don't have the time to understand complex messages.

Secondly, we desperately want convenience and control. The popularity of ATMs is a prime example of that. If you look at the adoption or diffusion curve for automated teller machines as it compares to credit cards, even though ATMs have been around since the mid-60's, once the ubiquity factor was addressed, the adoption rate by consumers skyrocketed, and we all know how quickly credit cards became accepted. ATMs became accepted at a much

greater rate, once they were convenient to use and available anywhere the consumer needed them to be.

Control is a factor we all have to have — particularly in light of how tough it is to earn and keep a dollar. We don't want to lose those precious units of our monetary measurement. The trust in brand names actually, we're finding, is probably the most important, particularly when you're talking about doing commerce in an environment where you're not face-to-face in being the counter-party to a transaction.

If you look at the brand names, that we know and love, and look at your own household, you will find several brand names, because you don't stand there and read all the fine print on the packages that the government says merchants have to put there. You try something, if it fits your need, you remember the brand and you use it again and again and again. And, I will tell you, that's becoming an increasingly important factor, particularly when you talk about consumers doing business with companies across an open network.

We all have rules as consumers, as businesses, and it is important to have a rule that says counter-parties to a transaction know what to do when something goes wrong, because something inevitably will go wrong. You get an error in your bank statement, you know what to do. You go to the bank or you call the bank, and if they don't satisfy your concern, you leave the bank.

When someone steals your cellular phone number, you know the rule. You call customer service and say: "The bandits got me" and they shut that number down and they give you a new one. The on-line services, the CompuServe's, etc., have learned to establish a clear set of rules when something goes wrong. They have adopted their business model such that, if their monthly subscription to your credit card comes back and it was returned by the issuing bank, they shut you off. They manage their risk appropriately. Consumers who are in the habit of doing that know the rules — they go get another credit card or they provide another means of payment.

So, it is important that, if you're transitioning or you're adding electronic commerce to the way in which you sell your product or service, that you communicate to your customer what to do when something goes wrong, and that will enhance customer satisfaction in their shopping experience — particularly at your store or your electronic storefront.

[In] talking to companies and individuals who intend to sell goods and services in [an] electronic open network environment, there are four key factors that we hear time and time again. I've heard these in the last 48 hours more times than I care to remember: we're hearing that you folks want to expand your distribution, but you can't afford to go out and build brick and mortar. Secondly, a number of you are pretty darned tired of paying higher rates for credit card processing and, not strangely enough, the consumer's well protected, as we heard earlier. So if something goes wrong with a credit card transaction, chances are pretty darn good that it's the merchant that's going to eat the loss. And for that privilege you get to pay a percentage of your sales — a percentage of your sales for eating the loss. That's a business model that I just don't understand.

So, what we hear is you want guaranteed payment. You want to know that, before you ship that \$50 item or that \$4,000 P.C., the transaction is not going to go bad after the goods are gone. That's particularly important when you're selling perishable soft goods in the remote open network environment — because that article, that piece of software, once it has left your server it's gone, you can't go back and get it. In fact, it's not cost-effective for you to go back and get it. You'll eat the loss. [It] reduces profitability and makes you a very unhappy businessperson. So managing the risks more effectively is something that's very critical, and if you're looking at electronic commerce, if you haven't found a way to do that, then I suggest you might want to take your time a little more carefully and rethink your standard risk models.

When it comes to marketing and sales, the promise of this new technology, this revolution, is that you'll be able to get more out of your marketing and advertising dollars by targeting those activities to pre-qualified buyers. I heard an interesting statistic last week that automobile companies have proven that they're willing to pay as much as \$300 to \$500 for a qualified lead. It's not surprising, when you're going to spend \$30,000 on a new car. That's what you need, if you're going to do business in an open network environment. You will have millions of hits, how many of those are qualified leads? So, you need to work on the distribution channel and on your marketing channels to encourage not everyone, but everyone who wants to buy the kinds of goods and services you have to offer. And that's an important factor in doing business electronically.

Finally, the question about remote transaction systems (he left the room for a moment) but we all need reliable infrastructure and technology. One of the most frustrating things for us, as consumers, is to stand in line waiting to run our credit or debit card through at the checkout counter, particularly the day after Thanksgiving and you wait, and you wait, and you wait. And it's even more frustrating when the expectations in the electronic digital environment are instantaneous gratification. So, you're right, you can never be down.

And, I'll apologize in advance [to] those of you in the technology sector or MIS functions, who think that high availability is satisfactory. No, no, no. You can never be down — that's lost sales and lost revenues. Very unhappy businessperson. What we've done with the CheckFree wallet is try to address some of those factors, and we don't profess to have all of the answers — we're in a trial phase of the new era and I would suggest to you that the \$200 million dollars, or whatever the number is, that's being spent on the Internet today, is just a drop in the bucket to what it will be next year and the following year.

What we're trying to do is stimulate and encourage trial behavior on the part of consumers and merchants. Our goal is to eliminate the risk in putting your foot in the water and trying electronic commerce. And we do that by developing partnerships and providing very attractive deals, if you will, to get you started. The CheckFree wallet — and I'll describe it in a little more detail later — is our implementation. It is both client software as well as merchant server software that is to be used either in a check free branded situation, or in a private label branded situation, that will allow consumers to purchase items safely and securely over the Internet.

There are two key value propositions, whether you look at the CheckFree wallet or [at] one of the other many payment options, because I will tell you there will be many and there will probably be more than there are today, we just haven't built them yet. We haven't conceived of them yet. But the first value proposition for the consumer has got to be to allow them to do things the way they do them today with the exception of standing in a store. They have to be able to do it when and where they want to do it. In the banking world, home banking was tried some 15 years ago: it was expensive, it was cumbersome, it was slow, banks got out of that arena.

Technology and the infrastructure has evolved, we, as consumers, expect our primary financial service providers to do business where we want to do it, when we want to do it and how we want to do it. Looking around this room I'd venture to say many of us can't remember the last time we were at a bank branch, except to borrow money and even now you don't have to go into the branch for that anymore. For the merchant, it gets right to the bottom line, how do I make more money, and that's why you folks are in business and there are a number of factors to that, but those have to be the clear value propositions in doing business electronically.

I'll run through some things in the CheckFree wallet. There's no charge to the consumer, there's no preregistration. Our experience tells us that when you go to shop in the

store, unless you have the store's proprietary credit card, you didn't preregister with the store. You walked in, you bought a shirt and you left. And, if we can't emulate that behavior in an electronic environment, the consumer will have an unsatisfactory experience. It has to be easy to use. We all know how to reach in our pocket, pull out one of those cards or some of that green stuff and lay it on the counter. We have to emulate that behavior in a digital environment.

[It must be] browser independent. We don't tell consumers which car to drive into the shopping mall, we don't tell them what bus to ride, what makes you think we'll be able to tell them that in the electronic world?

This is all I'll say about security, we have it, it works. We'll get better, there'll be more as we go along, but when was the last time you worried about what happened to your ATM card number after you stuck it in the machine? You probably didn't think about it. You probably thought more about the guy — who's my size — standing behind you looking over your shoulder, wondering whether he's going to hit you in the head.

We have to have records. We may never use them, but we keep lots and lots of records as consumers. The CheckFree wallet today is the initial implementation, and is a co-branded client application with Cybercash. CompuServe's *Mosaic in a Box*, that was released in late August, includes the wallet — it's private labeled as the *CompuServe Wallet*. Spy Glass's enhanced *Mosaic* will also include the *CheckFree Wallet*, don't know if it will be branded the *Spy Glass Wallet* or not, but it doesn't matter to us. Additional client applications, be they individual, stand alone browsers or CD-ROMs distributed by merchants, that have the entire catalog on the CD, or have the purchase capability built right in, and the *CheckFree Wallet* will be one of those.

You can download it, not only off of our Web site, but others. The point is that we're striving to make it readily available. The analogy there is the three or four credit card offers you get every week in the mail — if you're not getting wallet offers in the mail now, you soon will be. It has to be that ubiquitous. I mentioned providing a risk free trial for merchants: CheckFree's Consumer Bill Payment service has a two-way electronic mail capability built in. We've got somewhere around a quarter of a million consumers who use us to pay their bills every month. They communicate with us about three times a month on average. So, we said, "How can we put something we have, that not many other people have, which is this ability to host a message to that many consumers on a regular basis, with the merchants who have a need to have qualified potential buyers come to their site?"

First, we have to get the merchant up — we can't wait for all of the hardware and software and technology guys to bring ten thousand merchants to the Web. So, what we decided was to try a little promotion, a little merchandising, a little marketing. And beginning November 15th we are launching the CheckFree Gift Link, which is really a miniature electronic mall with a number of merchants who are putting one or two gift items on sale at no risk to the merchant.

There's no technology investment, we're driving consumers to the page, so there's not a whole lot of marketing that they have to do. And what we're doing is allowing them to begin experiencing what it's like to receive orders in this environment. It's essentially a no risk proposition. That's a short list of some of the merchants that have already announced that they will participate in the gift link. Victoria's Secret Catalog, Cheryl and Company which is known as Cheryl's Cookies, and, if you go down to booth 750 our sales guys hopefully haven't eaten all the cookies that Cheryl's sent to the show, go down and get a chocolate chip cookie on us.

The point here is that this is trial behavior. The marketing objective is to stimulate trial behavior and that's what it's got to be. We work with MC Squared, now part of an advertising agency, to allow companies like Victoria's Secret to sell one thing when they happen to be selling three different gift certificates across the Web, and to get some experience in that

regard. There's a quick shot of how easy it is — I can't show you how easy it is up here, if you go down to the booth, you can see how easy it is to use the CheckFree wallet.

I want to end — you'll get to see my screen there — I want to end with four key points. Get started now, determine the criteria for what success means to you and what partners you will use to get there; be prepared to fail, try again; and learn and fail again and learn and try again, because you will. And finally, celebrate whatever little successes you have as they occur, because this is not easy, it's hard work and you have to step back and enjoy it sometime.

Thank you.

David Fox: Thank you very much. We'll [take] just one question, if there's just one burning question someone's got, and then we'll move on to Pierre Wolf from First Virtual. Yes.

M: [inaudible]

Michael Slade: The merchant. Again, the merchant pays to receive payments today. He pays credit card rates, he pays to have checks deposited in the bank. You wouldn't dare catch me quoting a price in [an] audience where there's 300 people.

M: [inaudible]

David Fox: The question is: "How do the consumers register?"

Michael Slade: For credit card payments, there is no registration for the consumer. You get the wallet just like you would any other, a physical wallet and you load it with the cards that you choose to use to make payments, you put in your driver's license, which is essentially your shipping address. And there's no registration. When we add electronic checking in release 2.0 in June of next year, there will probably be a registration because the consumer protection available for checking account transactions is not as great as consumer protection for credit cards. We're very concerned about that, so there will be a registration process.

M: [inaudible]

Michael Slade: Sure. We are accepting image files of your telephone bill if you are a customers from Southwestern Bell, and people who are CheckFree customers can receive that image delivered to their PC. And when you're ready to pay it, you just say pay it.

David Fox: Okay, if we can just hold any other questions until the panel session. Next up, we have Pierre Wolf from First Virtual. Pierre is a great guy and knows a lot about what's going on in the marketplace. First Virtual was the first electronic transaction system that I set up and it's really something that I recommend everyone do. As Michael said, you've got to get started, you've got to become a user to become a seller. And, First Virtual has a great system, it's really easy to sign up for, and I'd really [re]commend doing that. And Pierre can take it away.

Pierre Wolf: I'm going to give you a little background about where I came from and how I joined First Virtual because I think it's important. I started... I was working with Reuter's New Media out of New York City and the task that was set was to start looking at the commerce opportunities for Reuter's on the Internet. I was in business development and it required meeting all the big companies who were doing things on the Internet as well as a lot of the start-ups. It was really interesting to see when I started investigating this in early 1994 that...

[Tape Change]

Pierre Wolf:... then about October of 1994, out of nowhere, I hear of this company, First Virtual. I'd never heard of them before and all of a sudden this became an issue. These guys weren't announcing something they were going to do, were announcing something they had just delivered and that piqued my curiosity and right away we set up meetings with them.

What interested me about them was [that] looking at the group that was behind this, the scientists that were brought together — how did this group come up with this pseudo low-tech solution? It's an e-mail-based solution. And, why would they have proceeded with that direction, especially with their backgrounds? Nathaniel Borenstein is a Ph.D. from Carnegie Mellon, he's one of the co-authors of *Mime*, if you don't know what *Mime* is, it's the multi-part Internet mail extension. It's used to transfer files — different types of files — across e-Mail.

Also, Marshall Rose was the author of SNMP, which is a simple network messaging protocol. And these are two very significant protocols on the Internet. And again, these guys were really bright guys, so why didn't they proceed with an encryption route?

I'm going to back up a little bit. I'm going to tell a little bit about the company in terms of background of why it got started, and how it got started and that will bring us forward to this. Now, first of all, I want to tell you that every time I do a presentation it's very spontaneous. Even though I have a slide show, I never know what I want to talk about. And it's because there's so much to say about the subject that twenty minutes doesn't do it justice. And in an hour, I can probably convince you that First Virtual's the best thing to do, but we don't have an hour, so I'm going to hit some of the key points and not trip over myself.

First Virtual got started by Lee Stein, Einar Stefferude, Nathaniel Borenstein and Marshall Rose. The meeting that happened was: Lee Stein is an entertainment attorney by trade, he had represented a number of rock and roll stars, and he was at LAX airport where he saw Einar playing with his PowerBook. And he came up to Einar — he had just been investigating the Explorer CD that Peter Gabriel was about to come out with, but he had been looking at CD stuff — and he said to Einar, "What are you doing there, is that multimedia?" And Einar looked at him, Einar's about 60/65 and he's been on the Internet since 1975, has influenced all of the e-mail standards that are available today, and he looked at him and he said, "No, it's the Internet."

And the analogy there is, it's not the bus, it's the highway. So, Lee proceeded to discuss with Einar, and said, "Where's the money on the Net?" And Einar crudely answered him, "Joke of the Day." And, actually I read somebody else used a similar example, actually in the *Out of Control* book by Kevin Kelly. But, the idea was that, if they could sell a joke a day to everybody on the Net for a penny a day, the economics of that would be pretty fantastic.

Lee, having an entertainment background, has a lot of contacts with people in the industry, so to him the Joke of the Day was nothing funny, he could actually realize this. And when they did the economics on the plane, they realized that they could afford to hire the Letterman writing team, the Tonight Show writing team and a number of other famous comedians to write the jokes for this particular product. So, content became instantly what they realized, that if they could sell low-value information on the Net — easily over e-mail, because e-mail is the largest common denominator — they could do a really good business.

All right, so that led us into [inaudible] as a result they realized that the opportunity was in content. They brought in Nathaniel Borenstein and Marshall Rose to start figuring out how [to] do a system that could be a commerce-based system on the Net and accept payments for this type of thing. In designing the payment system, they realized, "What a great idea — why

don't we forget about Joke of the Day, let's make a payment system company! Nobody will take us seriously if we start doing Joke of the Day."

As a result, they developed this payment system which really was addressing their needs for a particular application [that] they saw widespread usage for. The focus of the payment system was not to be a payment system for everything — it wasn't about hard goods, it was really focused on information and intellectual property products over the Net. Things that were deliverable over the Internet.

Part of the issue is that we're dealing with sight-unseen products. When you purchase something that you can't see what it is, as is often the case in mail-order, or telephone order, there's a high percentage chance that it gets returned — certainly higher than if you had seen the product. As David and I believe Cliff mentioned earlier, there's a charge to the banking network when that happens, which can cost up to \$50. To the merchant, it can be resolved into higher discount rates, as well as fees for chargebacks. So, the system was set up to try to address this as part of it. I believe [inaudible] people just haven't understood yet how to do commerce over e-mail to really take full advantage of it.

Our system runs over the Web, as well as over e-mail. But the key is that the focus we see, is that, for example, direct-marketing opportunities are something that today are not easily accomplishable with the existing payment systems — but with ours it's pretty simple to do.

An example would be a subscription system. Let's say I had a magazine subscription and, as a publisher, on the 11th month, I would send out a renewal form to my customers. They would then check "Yes, I want to renew," they'd put a stamp on the envelope, they'll put the little piece of paper into the envelope and they'll mail that off. Okay, that could be anywhere between a week and two weeks turn-around.

In the First Virtual world, what we would do is we would call this a merchant-initiated transaction. The merchant could initiate a transaction to the end user saying, "Do you want to buy this, 'yes' or 'no'?" That is because the merchant has the virtual PIN number of the user, and can use that to initiate the transaction. The consumer, at that point, would decide whether or not they wanted to buy. So a simple answer of "yes" or "no" to the question would fulfill the transaction. It's immediate. Now I need to explain a little about how First Virtual works for this to make a lot more sense.

First, we'll deal with the mission statement that Lee Stein had come up with, and it's basically where we are. [It] is: we're a financial and marketing company created specifically to enable safe, global electronic commerce by anyone with access to the Internet. In addition to that, it was important to be low cost, affordable, and that anybody be able to become a merchant on the Internet and accept credit card transactions. We do this by assigning a virtual PIN number.

So in other words, the credit card information never actually travels on the Internet on our system. What happens is the user comes to a site, they register, they pick an eight to 24 character I.D., then we send them an e-mail saying to call this 800 phone number and it's an automated system which will allow them to provide their credit card information over the telephone. Once that's done, we send them an e-mail saying, "Your account is active, and from now on, any merchant who accepts First Virtual, you can transact with."

To give you a little feel for our growth: currently we have approximately — I believe we've now crossed the 700 merchants on the system. We have, our user growth, we've crossed the 40,000 user mark. We're growing at the rate of 12% to 16% compounded weekly, which is very shocking and very strange to look at when we see these numbers on a weekly basis. Growth is phenomenal, so we know there's a need and a desire for people to do commerce on the Net.

The number of transactions per week, right now, is up around, I believe it's crossed the 8,000 number as well, and that number's still fairly low. What we're seeing is that it's still driven by people who are going to a site, want to purchase something, [see] that they need a First Virtual account to purchase it, go get it, then buy the item. So today, it's still people coming in to buy one thing, but they have a PIN number and it enables them to do recurring purchases. It's probably about an average of 1.4 items purchased per person so far.

Okay, I'm going to give you an example of how a First Virtual transaction works, it usually helps visualize how it would work. Reuter's new media has a company called Reality On-line, and Reality sells premium financial reports on publicly-listed companies. So, when you get this, there's a certain page on there where you can order these premium reports. They accept First Virtual, you go in and you put in your PIN number, and you select the symbol that you want.

The PIN number, by the way, although it's hashed, doesn't need to be. A First Virtual PIN number is not a hidden number, it's not a secret I.D. or a password or anything of the like. And you'll see why because of the process. So the report would come down, and then the — Okay, this is what the merchant sees once the user says, "Yes, I want to pay for this." Because prior to this process, what happened is after Reuter's sent the report back, they sent First Virtual a message saying this consumer bought this product for this amount of money, and we now need confirmation that they're going to pay for it. So the confirmation would go to the user and they would then answer "yes," "no" or "fraud," which are the three possible answers to the query, and then we send this upon the "yes" answer — this is what the merchant would get back — letting them know the consumer will be paying for that product.

One of the things that's interesting with a "yes," "no," or "fraud:" "Yes" means, "Yes, I want to pay for it." "Fraud" means, "I never made this transaction, somebody's misusing my card," and so we'll automatically suspend. The "no" is always a tricky one, because in sight-unseen materials, "no" can be one of three things. "No" can be, "I received the information, but it wasn't what I ordered, or what I thought I was getting." "No" can be, "I purchased and the download on its way down broke and the merchant may not have known that that happened," and the third "no" would be, "I purchased it, it's exactly what I want and I'm just not paying for it." And I'm using the "no" mechanism to say "no" instead of "fraud." That third "no" answer, we have some fraud detection software within our system which evaluates the merchant's site against the user's past behavior. It is not a manual process — it is a fully automated algorithm that we have and we're constantly refining.

So far, we've been about 80% accurate, in that for the people that we've gone after, about 80% of the time we were right, about 20% of the time it was an error on our side — where they legitimately went three times and said "no" and it didn't work.

But we're constantly refining it, and like I said, by about the third "no," we're finding those people. From the merchant's perspective, though, information products do not have a cost of goods sold. They have maybe the temporary "line-con" that you would use on transfer of the information, but you have a sub-cost when you produce an information product.

And, whether you sell one, or a million, your sub-cost is the same and your cost per good sold is not happening. So that if they do lose, let's say for example Reuter's downloaded this, somebody was defrauding them, and they said "no," — the maximum lost was just the opportunity costs. And chances are, if the user had to pay with a credit card, they never would have initiated that transaction if they were really looking to defraud the system. Even those types of "no's" are not incurring a real cost to the merchant.

Unfortunately, this did not come out so well. Apple was selling *QuickTime* using First Virtual — they recently pulled that out as a result of changing their software strategy and we expect to see a number of other things that they will be doing using First Virtual. But basically,

you would go to their site and you could buy a First Virtual *QuickTime* on-line. Basically the message would come back — this is what we send to the user — so it says, “Apple Link has requested that Beverly should be charged \$9.95.” At which point Beverly would clear out the body of her message and answer “yes,” “no” or “fraud.”

This summary here, once we’ve hit the credit card, which sometimes we don’t do right away, so it may be a batch operation and — actually this is a batch operation — it can take up to one or two days before we literally hit the credit card. There may have been several transactions that are accumulated there. But once we hit the credit card [or when] it went past \$10.00, we hit the credit card and we send the message saying that we’ve hit it.

This message also has a tracking number, which will appear on your credit card statement. And, actually, I believe that on your credit card statement, that initial tracking number up front only says — it’s only a one liner — it says, “First Virtual,” but that tracking number contains all of the information behind that. So you can query our server for it, but we also send it automatically once we’ve hit the credit card.

Okay, so the way we look at this is that first, when mail-order was introduced, these are all sight-unseen credit card transactions. When mail-order was introduced, the validations that were brought in were address verifications, for example (early fraud detection). Address verification, if you’ve ever tried to buy an airline ticket, for example, and you give them an address other than your credit card, chances are you won’t be able to do it.

Telephone order introduced the ability to do on-line authorization, so it wasn’t after the fact, it was right there, when you were giving your information. And First Virtual adds another layer there, which is really bringing in a[n] authentication by e-mail so that, for example, if somebody had misused your card number, or your PIN number, you would have known right away. As well as the fact that we’re using the PIN number for validation — enabling the merchant to quickly check that your PIN number is an existing PIN number and then, finally, that we get instantaneous fulfillment of the product, so that you don’t have to wait to have it shipped to you later on.

What I want to hit next is the actual First Virtual process, looking at it from a chart perspective. So, what happens here [is that] the customer will give the merchant a pin number, the merchant sends to us the information, which is the customer’s pin number, the merchant’s I.D. number, a summary of what was purchased and the total amount of the purchase.

We then take that and send it in the form of an e-mail to the customer. The customer, then, replies to us with the “yes,” “no,” “fraud” system. And, if they say “yes,” we then batch it down to [a] secure credit card system. This batch line is a custom protocol and it’s a batch protocol, so it’s uni-directional and does not actually sit on the Internet. The machines below this line, we call the “below-the-line” system, as opposed to the above-the-line system. The below-the-line systems are not on the Internet, so no credit card information is ever exposed.

First USA is our acquiring bank, our merchant bank, so that once we’ve passed it through the EDS system, it will go to them. We would then... the money transfer goes through our ACH transfer agent, Northern Trust, and they’re the ones who actually do the bank transfer. Then, eventually to the merchant’s bank account as well as to ours.

The transaction cost to our system is 2% plus \$.29. The 2% represents the standard credit card discount rate. For most credit card merchants, the rate is anywhere between 1.25%, depending on how large [the] volume — department stores for example — to mail order, where it can be anywhere between 4 and 5%. So, we do 2% for everybody, regardless of the size of the merchant. The catch here is that in the case of small merchants, who would not normally qualify for merchant accounts, we have a 91 day hold that First USA imposes on the money. And the reason for that is because then each consumer has a capability that within 90

days of a transaction, they can cancel a transaction completely. If that were to happen and we had paid the merchant... well, let me give you a scenario.

The scenario is a number of customers and merchants collude against First Virtual. And the way they do that is they initiate a number of transactions, all the customers say, "yes," and then it goes down to the credit system, and everything is okay. We pay the merchant. 70 days into the transaction all the merchants go out of business that were involved in the process. 80 days into the transaction, all the customers that bought that product come back and say, "We want our money back." And so a chargeback occurs — First Virtual would be held up there.

Now, while I worked with Reuter's, that was a problem for me to see 91 days holding that money. The cost of money to us was a little too big for that. So what we were able to strike with First USA is an arrangement, that, if a merchant is able to qualify for First USA's merchant account, at that point we would do immediate settlements.

So, what that does, is that, for the larger companies that already have merchant accounts established, they're able to deal with it in our system and get immediate settlement. For those smaller merchants, who are just starting out or who are individuals who want to sell products, they would go through the 91-day route.

So we have a number of strategic partners with us today, First USA being one of them. And, it's mainly because the First Virtual PIN system addresses the needs of a lot of these people. In the case of the banks, like I said, especially the banks — with these chargeback issues — by being able to say, "no" to a transaction before it ever hits the credit card, it enables them not to have the chargeback cost that is associated with that.

Until recently this had been one of the problems that we had seen that First Virtual really addresses well, and it's the issue of browser security at the end.

The information traveling between the two points may be secure, but, what happens to the credit card information once it gets decrypted in the merchant's machine? If the merchant is not running a 24 x 7 shop, we were concerned that that's a point of attack. And in the case of the CERT, which is Carnegie Mellon's Center for Emergency Response Team, they issue about ten batches a month right now to HETP servers and things of that nature. Which to us, is again, these are exposure points, that when you're not holding credit card information at that end, and only PIN numbers, you really don't have anything to worry about.

(This should read STT.) This is a slide that we normally use just to illustrate what the STT protocol looks like right now.

Now in the issues of security, this is something that we kind of take pretty seriously. And, we have a couple of opinions on it, and I want to share those with you because it's relevant to what we're talking about.

First Virtual is a process-based security system, as opposed to a technology-based security system. And what I mean by that is that, what we're relying on in encryption security is that the technology is sufficiently strong enough to protect from intrusion of the information. If the encryption wasn't there, then the security systems wouldn't work.

First Virtual's system is process-based, which means it doesn't rely on the technology. I could do the First Virtual process — that I showed before — with a telephone, and if all the parties had telephones, I could do the entire thing with telephones and it would still work. I could deal with a telegraph machine and it would still work. So the bottom line is that it's not the technology that we're counting on — it's the process that we're counting on.

As part of that, for example, if you wanted to defraud the First Virtual system on a large scale, you'd have to basically hold onto every... have access to everybody's e-mail account, and be able to lock them all out of receiving the e-mail from us.

And, again, in a technology-based solution, if I understand how to break through the encryption and/or find the bug that leads me to getting to that information, then one of the

fraud issues that I think is the biggest is that I could hit every credit card one time for a small amount of money and never hit it twice. The credit card fraud systems are not set up today to deal with that type of fraud. They're set up to deal with abuse of one card, but not abuse of multiple cards for low amounts of money. So this is another issue that I think is being brought when we deal with security issues.

For those of you who were able to get the folders at the back of the room, I have a copy of all the slides in there. If I didn't get one to you and you'd like one, please give me your card, and I'll make sure you get one when I get back.

Okay. So Lee Stein, he's our CEO currently. And Marshall Rose, as I mentioned before, he's the author of SNMP. Daniel Borenstein, author, co-author of Mime. Einar Stefferude, he and Lee were the two who really got this started. Einar recruited Nathaniel and Marshall.

Okay. I think I'm done right now. Sorry for the awkwardness, but thank you very much.

David Fox: Now, if you've got a couple of questions for Pierre, then I'll introduce Robert Hettinga. And while we're taking those questions, what I might do is just pass around a small box, into which you can put your business card. And again, we've got a couple of copies of this *Digital Cash* book, [inaudible] by Peter Weiner on AP Professional, if you'd like to win one of those two copies, I'll pass around a box. In the meantime the questions for Pierre.

M: So, what happens with Joke of the Day if you have \$.29 at 2%, are you effectively shut out of small...

Pierre Wolf: Yeah, and the problem was that when we, did this system, we went for the lowest cost possible. It cost... the merchant cost \$10, one time for you to register. It cost the user, consumer \$2, [as a] one time fee, and with this 2% of \$.29, that was the lowest we could do and still make it work. So that a lot of times we get a lot of static, "Well, can you waive the \$2 fee, can you do this?" These were all the lowest numbers we could reach and still make the system essentially work.

M: So is [it] still aimed at small information...

Pierre Wolf: Yeah, what we recommend for those people is that they use an aggregation model. So that they aggregate the transactions on their local server and maybe, say, every \$5 or every \$10, bill the consumer, or make them pre-pay and work off the \$5 or \$10 until they get...

David Fox: I [inaudible] the questions and I'll introduce Robert Hettinga. Pierre Wolf commented to you [inaudible] that you get more e-mail from Robert than anyone else. [inaudible] some interesting views on [inaudible]. Make a couple key points and then we'll take another question. [inaudible].

Robert Hettinga: Hi, I'm Bob Hettinga. First of all, now that half of the people have left the room, why don't the rest of you get up and stretch for a minute. How's that? Might as well take a break right [here].

M: We're going to be here that long?

Robert Hettinga: We're not going to be here that long, but I figure I'd give you all a break.

[A several minute gap in the recording occurred here.]

M: [inaudible] I'm always very annoyed when I do not receive an invoice if I pay by credit card, but I don't receive a receipt or an invoice, which I can hand in on my tax report.

Robert Hettinga: So that's my question essentially. How do you take international...

David Fox: Okay. Well, each of the members can address that, starting with, starting with you, Cliff. I understand the point of being formerly... being an international person myself.

Cliff Utstein: From an international perspective in the architecture — where the front office is separated from the back-office — we are currently working with transaction service providers in Europe and in Asia to run back-office services. And those would be customized for the habits and in models that the consumers and the businesses are currently using in those locales. So, if they wanted to send the credit card over the Web, they could.

But again, on the back-office model, you can do it by fax, or you can set up your accounts via telephone or another mechanism. So, as soon as the transaction servers take the back-office in Germany, you're set. There's no additional encryption required. The digital offers and digital receipts in the front office/back-office, are not encrypted. They're actually just hashed, using an MD5 hash, and that's fully exportable.

Pierre Wolf: First Virtual is currently... our system has been [inaudible] in its infrastructure it supported multiple languages and multiple currencies. We're currently have a discussion list right now, because we've had a lot of interest from outside of the U.S. In that list, we're discussing what are the issues in so far as card activity to the banking networks, that need to be addressed in each of the different countries.

Today, I'd have to say that the Japanese have been the most aggressive with us in so far as getting the stuff.

Michael Slade: CheckFree is already processing, on a pre-authorized basis, local currency transactions in the U.K. Beginning in three weeks, we also launch [a] service in Germany and France. By the end of the first quarter we'll be in nineteen countries, both in Europe and in the Far East.

All the issues you raised represent a tremendous learning challenge to anyone that's going global. It's not just a payment processor, but it's also the merchant as well. And notice I said, "Global." There is a difference between being global and being international, because you have to learn the protocols and rules of doing business in each and every country. The problem is that the infrastructures and the regulations are very protective in any country around the world. And that, [as] David mentioned earlier, the regulatory world hasn't caught up with the market realities. And that's very true today.

The CheckFree wallet — even though the existing protocol we use has been certified for export by NSA — it's a 768 bit key. That's not half bad. The problem is, is that there are very different rules and requirements around the world. And if you're going to do business globally, you'd have to be proficient in doing all of those, and we're learning.

David Fox: And we'll take a final word from Robert...

Robert Hettinga: Oh, God.

David Fox: On this global...

Robert Hettinga: Giving me the final word.

David Fox: And then I'll, welcome [you] to come up and talk to us individually.

Robert Hettinga: There is a concept that we talk about on the Net called regulatory arbitrage, and that is: moving stuff to different jurisdictions. Having to deal with the fact that you've got all these governments, which really don't know anything about the Internet, and are trying to regulate it. There are lots of problems with the rules out there, and the problem is, of course, the network doesn't have a lot of rules. And the more rules you put on the network, the network tends to treat it as an obstruction, and it tends to route around damage. It tends to treat censorship for instance, as damage. So we have a problem, but it's not a problem that we can't handle in the long term.

The other thing about currencies is the new iteration, the first iteration of Digital Cash came out of Mark Twain Bank in St. Louis and they have, the accounts that they have, you can put in seven or eight different currencies, and I also believe they do it in the Deutsch Mark, so you can get around it a little bit that way.

[Tape change]

David Fox: You're welcome to come up and speak to us individually. And good luck in your transaction search.

INTERNET TRANSACTIONS SECURE COMMUNICATION AND COMMERCE OVER THE INTERNET

MODERATOR

Bill Washburn

Senior Vice President, Internet Business Group, Mecklermedia

SPEAKER

Amir Herzberg

Manager, Network Security Group, IBM T.J. Watson Research Center

Bill Washburn: Ladies and gentlemen, I know this isn't a session or series of sessions about the ins and outs, the research on audience geographical distribution in a room; I want to advise you, however, at this point, that the presentation will be on overhead and therefore will only be visible on the screen to my left, which I believe would be your right. There's plenty of chairs to that side of the room so feel free to take appropriate advantage now, or later if you wish. That's entirely up to you.

I certainly hadn't intended to introduce Amir only to have to depart the room, but unfortunately I am, for better or worse, serving double duty with the news media, and it turns out that there is rather more interest in the press of various sorts than anyone had anticipated. I have to do some other things while this is happening, so at this point I'm going to just say welcome to you and this will be an interactive session to the extent that this is appropriate for the speaker and for you. I'm sure that you'll be able to work this out amongst all of you — after all, we've had all that training in how to be good students. Unfortunately it keeps a lot of good interaction from happening, but maybe this won't have to be so today.

Once again it's a pleasure to welcome you to this series of sessions, and in particular we're in the session called "Secure Communication and Commerce over the Internet." We all know, everybody's talking about commerce on the Internet; I would only — maybe less, for now — with respect to the Internet, in the sense that there are so many ways to be valuable as a Web operator or to have value in a Web and Internet environment within the commercial community without trying to do commerce in the business sense of exchanging money. Nevertheless, that's not what people like to hear about, or at least like to talk about, it seems.

So I would like to introduce Amir Herzberg, who is Manager of the Network Security Group at IBM, at the T.J. Watson Research Center which is in lower New York — although it's called upstate New York for some reason. I'm from the west and it struck me as interesting about that Westchester county area being upstate New York. So ladies and gentleman, thank you very much, [and here's] Amir Herzberg.

Amir Herzberg: Thank you. I hope everybody can hear me and I hope you will know that you can see this, and since we're such a small audience here I would welcome very much any questions and so on, you're very welcome to ask. I suppose that the reason that we actually have a big crowd is that this is a double feature. We have two things here, secure communication and secure commerce.

Before I begin I'd like to give a small overview of what my group is, just so you understand better who you're talking with. I'm from a managing net for the security of the IBM Resource Center, one of our resource centers, and my group is focusing on actually applied cryptography, one would say, which includes actually focusing on Internet security and electronic commerce, and not just on the famous [inaudible]. We see commerce as a much bigger thing, but today we would focus on the payment part of it, which is an important part of what we are doing.

Other areas we're working on now include secure mobility and cryptography in general, including theory and [inaudible] cryptography — we're doing a lot of work in this area. And one particular example of our advanced work in cryptography is a new earlier [system] which we have kind of created or are creating, which we call "proactive security," where we investigate methods where you can have security without a series of any single server — any single point in your system that is secure forever — but actually distributing your security among many different sites and running protocols periodically on all these multiple sites, pictographic protocols, so that even if every site could be broken the attacker really has to break into all sites at the same time in order to break your system.

So this is just to give you a bit of a flavor or where I'm coming from. I'm coming from really advanced research in cryptography, but also trying to find applications and help IBM products and customers.

So what we're talking about today is a double feature. In the first class we'll talk about advance results in securing communication across the Internet, where essentially I will focus on a particular mechanism — if you're securing communication in the IC layer between two IC networks or two IC hosts, which is a reason [for an] Internet engineering tasks for the ICF, which is [the] Internet group trying to establish a standard as to how we do this, how we secure the communication across the Internet.

We are involved in this process, so I will describe that briefly to you. Then I will talk about — in fact I will put more of our time in discussing security for electronic commerce, and in particular for payment. I decided that of the two parts this should take more of the time for the simple reason that I noticed they put me on the transaction track, so I guess everybody decided this is the topic I should focus on. And then there are recent conclusions; but I will try to actually leave some time for questions at the end. But you're also very welcome to put questions into the middle if you want to.

The first question when we look at securing communications, security in general on the Internet, is what is the right layer? Where should we position security services? Here's a traditional question that people are debating about. In fact, it's a very important question, and if we had the time we could spend a big chunk of the talk just on this point; it's one of my favorite ones. But we won't.

What I want to point out to you is that security actually should be embedded in more than one layer. In some ways security in different layers can complement each other and have different advantages. Some advantages are things we should have for a conditional period, but it is maybe meaningful to have security some place until we can have more products in the different layers, some things that are really there to stay that we really need even in the long-run security mechanism in different layers.

As we begin the application layer, traditionally we say that it's best to have security in the application because it really deals with the end-data of the user, and that is true. In fact there are some security functions that you can do only in the application because they are really very much related to the semantics of your data. For example, signature — you don't want to sign everything that you send out. In order to sign you have to know what you are signing. In fact, it may even — and I don't want to get into the [details] — but in some cases, if you sign things without really being aware of the need to sign these things you may do a disservice to the user and even cause security problems. So signatures are an example of something that you can do only in the application layers.

And there are other examples, like very strong encryption and things like that. However, there are disadvantages in doing things in the application layer. One of them is efficiency. You have to do things only in the application. Another [disadvantage is that] it's difficult to gateway, to drive a central point like a firewall or something similar where you

provide the security for the entire corporation. This is something which is difficult to do if we do encryption in the application — namely, to capture the transaction on the way. To get it up to the application at the firewall is a difficult process. Also it will require us to change all applications and to trust that the user would, in fact, change all applications.

So for things which require knowledge of the semantics of the data, it is more efficient and more secure and more manageable to put security in a lower layer which will capture all of these things together. It's one chunk, and that's really what we talk [about], a secure tunnel between the two sides or between the two networks and so on.

Now, when we talk about having something like that, just a pipe or a tunnel to provide security, we could still do it in different layers. We can do it at the [inaudible] layer, which is what SSL, for instance, is doing. It's a thin layer which is close to the application, it's relatively easy to implement, and you don't need to change the [functionality] of your system, it's easier to implement. But it still has also a lot of disadvantages of doing things in the higher layers; it's less secure, you're still depending on lower layers being secure from hacking attacks and so on, it is less efficient and so on.

And that fallacy, that there isn't a standards body which has essentially adopted what we want in the long term... Is there security in the IC layers? And in fact, that is what we're interested in going towards, because it provides you with highest security and highest performance. It's the cost of requiring all vendors to implement the same thing, and that's the small comment over here; to do this efficiently we really need a standard, and that's why we work very hard in this body to reach a standard agreed between the different vendors.

In fact, right now you can go and buy many secure firewalls that would provide you encryption capability but unfortunately don't interoperate with each other, except for the upcoming firewalls which would support this Internet standard. Ours is one of them; ours is actually already available. It's [release] was exactly last Friday, and I know at least one other company which we've already tested interoperability with a [inaudible] and I think that they are going to be out there very soon. I didn't check with them exactly about what was the date. We're working a group of many firewalls to make sure that all or most of the firewall vendors would, in fact, gradually implement this standard and interoperate.

But the standard, by the way, is not limited to firewalls, and certainly we hope that we and others would implement it also in end systems. Just a small mention; why don't you go even lower in providing security at the link layer? The reason for that is because we don't control the internal links of an Internet, and therefore we cannot really go lower than the IC.

So what we are talking about is secure IC coming in over the insecure Internet, and what we are working at is to implement this and to service the Internet standard in the IC [inaudible] group. And this is two main things, the distribution of the [decryption key], so it's key management, and then encryption, which is done by encapsulating the IC circuit in an external IC circuit, so it's IC and IP encapsulation. And the standards wouldn't allow us to use either public key distribution or a key distribution center like [inaudible].

The standard does support both of these options, and it could be used for secure [inaudible] communication or for private venture networking over the Internet. And the emphasis is on openness, of course, on security. In fact, the standards really take very high walls in security, which I'll talk about briefly, and efficiency. The figure will look something like this. Okay, it will look something like this, and you could have two sides and they are connected with this firewall or with encryption tunnels, and they secure all the communication between them. And this is actually a miniature firewall in a home device or a mobile device or just an end machine, so you could have it also, of course, inside the organization.

Just one example of something that this will prevent against. We recently heard about this Berkeley student attack against SSL and file systems, other security mechanisms which used

a network snoopers essentially to inject messages into the network and change software with a slide. If you had an IC tunnel between the end systems and the file server this would have been impossible.

A few words about the requirements of these protocols. The first word of these wonderful [inaudible] is simplicity and so on, and their action is the same as we always look for in an Internet protocol. We always want these kind of things in an Internet protocol. The second is really the focus of this particular working group, and we really decided in the working group to have high security requirements from this protocol; this is like the base security protocol of the Internet. It will be a part both of IC [inaudible] as an extension, and early from the beginning in the next generation of the IP, IP version 6.

So requirements are really strong and the design is based on very conservative principles and conformance in a modular way. The design would allow us to replace any components if [they are] broken, and allow us to [take care of] some greater concerns. The design improved some sound mechanisms for recovering from exposure of [inaudible], limited recovery from exposure, which actually relates to, if you remember, the beginning of working on proactive security and recovering from exposure. But this is to a much more limited extent.

In fact, we are just in this day finishing the theoretical design of how to do proactive security for communication, so this of course is not meeting the standard. There is contained protection against somebody just sending you a lot of garbage and trying to cause your machine not to be able to handle all of these connection requests. Remember that cryptography and public key management in particular involved substantial overhead and computationally expensive operations, so we have some mechanisms to prevent somebody from sending a few messages and causing us to waste a lot of cycles. There is some cloning protection, and there is some on the limited mechanism in the protocol.

Now, I can go into details on the design, but I think I will not do that. I wanted to talk some more on the other features of the talk, so I'll just hit on the status of these things. The encapsulation mechanism for packet encryption and authentication are at the first standard level in the Internet if you [inaudible] standard. So it's an RFC, it's a standard trick, and it's a first level of the standardization process. It could still be modified, although we don't expect substantial modification.

The key management aspect we are still converging. We hope to converge to a standard [inaudible], and we are trying to reach that goal. My hope, my customers' hope, is maybe that at the first opportunity next year we'll have it standard. But even before we all have interoperability at least we've [established] our key distribution between systems. And that's what we are doing, as I said, with some other vendors.

Performance is really very good, very satisfactory. We have already one product announced and available, which is the IBM Internet Connection Secure Gateway. You can get more information on it downstairs, or actually I have a few sheets with me if somebody's interested after the talk. And as I said there will be other interoperable products from different inventors. Any questions on the first feature? You can wait until the end of the talk, of course.

M: [inaudible]

Amir Herzberg: Well, we have many customers. The question was, why would anybody care at all about interoperability between different firewalls? And the answer is that we have many customers who would like to... Even in their own network they may want to have different firewalls for different parts of their organization, and then they may want to have the flexibility of buying from more than one vendor. Actually, a lot of our customers are very concerned about open systems and allowing themselves this flexibility.

In addition to that — and very importantly — you could actually use these secure panels to connect to another company which has selected a different firewall, so maybe you have the hope of establishing this new company. You only buy IBM firewalls, and that's a wise quality. But maybe there is some other company, not to mention the possibility of your CEO suddenly overtaking another company, where this other company — we're familiar with this problem — this other company would buy someone else's firewall. Well then, wonderful, they do interoperate. You could actually secure a communication with this other company across the Internet. So this interoperability is very important. We hear it from our customers all the time, they care a lot about that.

And for firewall vendors, talk with me afterwards. There is a firewall vendors mailing list and we are working together trying to have this interoperability among us, and other vendors who are not involved and would like to get involved are very welcome. One more question now, and then some at the end.

W: [inaudible]

Amir Herzberg: Yes, our products will have an exportable version which will also have encryption, but weaker encryption, unfortunately. It's not that we want to do, as you can easily imagine. But yes, the encryption option that is outside the United States would be weaker. It would have encryption but it would have weaker encryption.

W: [inaudible]

M: Well, you would have it with the weaker encryption. However, if you would want to use a strong encryption — actually, we are trying to find solutions to that. The best solution, of course, is for all of you guys immediately after this talk to write a letter to your congressmen, and that's the best solution. And we are working on that solution with our congressmen; IBM as a corporation is doing that. But more people should do that. I think that these export restrictions are not helping the United States. But yes, we are limited, and maybe, however, other vendors from outside the United States may also make this an interoperating standard. Again, other companies would be able to buy this from other vendors. Unfortunately, I hope they'll find there isn't a vendor — and there are some other good vendors — and then they will be able to interoperate with our product in the United States.

Now let's move to secure the electronic commerce. So we believe that the Internet is a very vague thing, actually. The way that I see the Internet is that the network receivers can communicate within this, and the network can send messages to other people who are connected to help everybody understand the Internet. So it's clearly a very fuzzy thing. People say, "Why isn't Internet on cable TV?" My guess is cable TV will be a part of Internet when data comes to cable TV. So this would be if the marketplace were the [inaudible], and I say this in the broad sense of the word. We see this as a huge condition in the business, in the same way the entire computer marketplace is much more than computers. So it's a very big thing.

And we want it to work, we want it to work as soon as possible and as well as possible. We believe that for us, IBM, the number-one benefit will be if this market really doesn't go in the open where it's unrestricted; then we will gain a lot from this, because we have a lot of services that we offer, Internet services, Internet connectivity services, IGA. We have many Internet products, we have hardware products which will benefit from this. And of course we've got software products.

So what we want is for this market to flourish; we don't want anybody to stop it. Security is one of the major concerns so want to address that, and in particular secured

payment is one of the concerns we want to address, and that's what we focus on today. And our goals are to have an open market, to have standards and interoperability. That's really our focus. We don't want to gain a small advantage to our sales, but then help this market much more. Because we believe that all will benefit if this market will grow and flourish.

One of the things we also want to do to make this market flourish is to look carefully at migration — how we enable people to move from what they are doing today to what we want we want to enable in this electronic marketplace. So this I will focus on, and you will see that also in our design it is a big focus.

There is [inaudible], and in the short term we want to keep it simple and focus on 20% of the problems, which will give us 80% of normal activity. You know what I mean. Therefore the conclusion for that, our conclusion is that we begin by focusing on charge cards, providing the payment solution for charge cards. We feel this is the simplest thing to do because it's a common mechanism that everybody is used to, and you extend the distances that people are used to having to pay.

Still, we are used to paying over the telephone with credit card, and that's a basic thing. The credit card is the basic mechanism to doing payment electronically when you don't have a face-to-face interaction. It doesn't mean that we don't try to support other mechanisms that work, and you do — we are involved in other efforts as well.

So how does that look? How does the credit card picture look? Okay, [with the] electronic banking system, the credit card electronic banking security is almost like this. We have the buyer who is the credit card holder and the seller. Now, each of them has his bank; the buyer's bank is the issuer, the bank who issued you the credit card, and the seller's bank is called the "acquirer" — for historical reasons we think it's called the acquirer of the seller.

The bank is essentially giving the plea to go get the money. And they connect with this information network, and this is an example of our migration approach. This network always exists so we don't try to change it. If it's something that exists we don't try to change it because it's much easier to build on what exists. What is different is not that this buyer, seller and acquirer try to talk on an open network, an insecure network; and the buyer has to somehow pass the money over and get the services and goods [through] this medium.

So that's what we're going to change, we'll do it [inaudible] between the buyer and the seller. And this is part of our main work, the certification forces, which certifies public [inaudible] of some of the parties, as necessary. So it's mainly this new path in which we don't have so far [to go], although it may be operated by probably the credit association, but it is not a good thing today. And see all the calls here, which is for some fancier aspect of the protocol. You can actually prove that you bought or didn't buy and so on in this protocol, because you really get a signed receipt and stuff like this. So you could actually say that the call system is, in some sense, layering the protocol.

So there are many... Actually, why are we doing this? Because there are so many proposals. Why should we just add more proposals? And this is just a very partial list of some of the payment systems that have been proposed or built, and so when we came to this we didn't necessarily say that we needed to do anything, but we realized it's not the case.

We found out that these general security mechanisms work end to end between the buyer and the seller, but they really don't provide you with any security above giving the credit card to the seller. In particular, there is no way to make sure that the seller even does this, and it is actually very difficult for sellers to tell buyers, "Hey, I'm not willing to sell to you unless you're using these encryption protocols." For the seller there isn't much of an incentive to do this if you think about this and the risk mode very carefully. The incentive is really for the creators of Communism, and the seller doesn't mind.

So we need a mechanism that will give the sellers an incentive to be more secure. Well, one incentive that we do provide to the seller — actually, there will be two incentives that we will give to the sellers, and I'll describe them afterwards — between giving advantages to the sellers over just using this basic seller to buyer security mechanisms. And these will be incentives for sellers to actually move to these more “three-party” protocols.

There are [inaudible] solutions and they are most known at First Wilshire, where you just open an account with this new entity. First Wilshire, for instance, performs a check, not [inaudible] but essentially by calling you back using e-mail. They could even use phone, I guess, for calling the buyer back and verifying that this transaction has been done. But this introduces a new cost in the system, a new bottleneck in processing costs in the system, and if you think about it carefully it doesn't really offer you a lot of security except the one fact that these numbers are not equated to a number, which is a very important point; I fully agree with this.

But then if we could have a solution which would be based on the existing system, it will be more efficient and more secure at the same time. So that's why we're not satisfied with this kind of solution. And again, I should emphasize that I'm really talking about what we want to see as these solutions. I'm not saying it's bad to use some of these existing mechanisms right now; in fact, I think that merchants should. I encourage merchants to start selling stuff on the network with the existing mechanisms. Don't wait for the best mechanisms to be available; [start now] and then move on to the better mechanisms when they are available, which would be pretty soon.

There are anonymous mechanisms. Not so many, but there's a lot of talking about mechanisms which provide you not just with payments but with anonymous payments. Using IC nobody can trace your payment and know that you've paid to get particular vendors. Supposing that you really want to buy from IBM but you don't want other people to know about it; then you can [with IC]. It's good.

Now, the problem is that these mechanisms are more complex, and for several reasons we believe it will be more expensive than the existing mechanism. One reason is that you need a whole new infrastructure with a whole set of bigger problems, so again you don't fall in our 80/20 rule in the sense that we believe that the problem of anonymity, the amount of shopping that people are so concerned about is not 80%; it's maybe the 20% but it's not 80%. So we want to focus on the 80% where we want to have a good, efficient mechanism for normal shopping.

But in fact, let me say that our mechanism that we design does actually offer you a possibility to provide a certain level of anonymity, which could be all that you need. We have to see about that later. They do offer you some level of anonymity — but not as perfect as [inaudible] cash, and therefore without all this, of course.

Shared key cryptography solutions have the following very basic problems. If we look at this existing network, if we use the shared key it means that the acquirer must have some shared key with the buyer. However, right now there isn't any trust relationship between the buyer and the acquirer, so we really need to change the relationship of the change that's happening here, although we say we don't want to do this — we want migration, we want to keep this system as it is right now.

So we have to go a public key system. Unfortunately, here we didn't find any published systems. So now it's different, but when we began we published I-KP which was the original name of our proposal. Now it's called SEP because MasterCard, in their infinite wisdom, decided to change their name — so none of them were published. So we said, “How would we have an open interoperative standard if nobody's publishing the protocols?” We've never had it. So we went and published a protocol, and that's what essentially we did.

And recently Microsoft and Visa have also published another protocol, so now we actually have these two, STT and SEP, which are both in this model. They're pretty similar; one Microsoft and Visa, one MasterCard and us and Netscape and GTE and CyberCash and the open market. These other proposals, I-KP — actually I-KP is the same as SEP — and the CyberCash system, where the secure carrier is Netscape who also designed some I-KP, actually have all converged together into the SEP proposal. So all that we need to be really happy is if MasterCard and Visa would somehow manage to agree to converge their two proposals.

[I want to talk] just briefly about SEP and I-KP. To those of you who are familiar with I-KP and wonder what the differences are, believe me [there] aren't many differences. SEP is really I-KP; in fact it adopted the 3-KP model, and now we'll probably also add the 2-KP model. To those of you who aren't familiar with that, "I" stands for one, two, or three in I-KP, where it means the number of parties who have certified public keys. I-KP is if only the acquirer has a public key. 2-KP is if the seller also has a key, so both the buyer and seller would have a certified public key. And 3-KP is also where the buyer would have [a public key].

Certifying public keys solely for the buyers could be a big problem. Many people are concerned that if there is expense involved, if the process is involved, if the customers may be afraid of that and may not understand it, it may take some time to for us to get certificates to buyers.

The solution is that we would begin maybe not with I-KP but begin with 2-KP, where only the acquirers and the sellers get certified public keys from the certification authority. And later we will move on to 3-KP. Somebody could, of course, get the certificate issued in a bank, and that will mean bank-issuing quality, so the issuing bank will decide if we're starting immediately only from 3-KP.

This is first of all a set electronic transactions, and secondly whether it's a 2-KP or a 3-KP it would allow us to have a different pricing mechanism. So these things actually will be cheaper than many of the transactions, and 3-KP will be cheaper than 2-KP because the risks are lower. That's a way to motivate the sellers to use such a protocol, because they get a lower rate, hopefully. MasterCard promised this many times. I'm not controlling the rates, but we have their promise.

Also [there is] the issue of converting to 3-KP because they will save some money, so we have this incentive mechanism to gradually migrate into the right solution, which I think this is really the philosophy that we are taking — to think about the marketplace and think about people, and show a smooth migration [path] between what exists now and where we're trying to get to.

Okay, so that's the 3-KP stuff, and that option extends right at this space in different ways, so it's essentially the payment [inaudible] and other stuff like some sophisticated things and some limitations that were not there. So it's really an extension of it, and it's an agreement between all of these companies.

In fact, now we should add resale and open market to this list. If we have [inaudible], we will do it. And we're going to submit it to guys here in [inaudible] format, and this is a big document. We should develop it, of course, on the network but it is not in that specific format that you're asking for, so we have to format it and so on. And we are editing a new version now, so when we're done editing we'll do the formatting, and send it.

Now, if you have been comparing separate [inaudible], how do we do this?

W: [inaudible]

Amir Herzberg: Oh sure, not that they're important but I will. Fine. SEP is Secure Electronic Payment protocol, I-KP is either I for one to three, and K protocol is — you can call it Internet Key Payment. And STT is Secure Transaction Technology. Okay?

So now let's compare them, and this is, of course, my very personal and slightly biased view, because I always look favoritively at the things I'm doing, so you should understand that. So the two protocols are really very similar: they are similar in their goals; they're similar in their approach; they're similar in everything. And the differences that do exist — and they are important, the differences — are, I believe, due to the design forces. STT was really a very, very slow design force. When I sent I-KP to Microsoft — they asked for it not more than half a year ago, and we sent it to them — we also said, "Well, why don't you send to us your stuff and we can start to compare?" [And they said], "Well, not yet." And we got it a few weeks ago, you know.

And in I-KP and SEP it was a very open process; we sent it everywhere, I wasted all of my time presenting it all over the globe, here and everywhere, and that, I think, caused some of the differences. So I think SEP used standards more than STT. For example, they sent us one, [X500], [Federal Nine certificate] and so on, and other standards.

[Tape change]

Amir Herzberg: ...most of your design, it was certainly much more widely reviewed and is reviewed, especially the I-KP part of it. We have some concerns about STT. I'm not going to bad-mouth STT, but we are trying to — actually, I'm surprised we didn't do it yet — I'm trying to get a meeting with and discuss this with the STT folks. Nothing as dramatic [as something] that could not be fixed, of course; everything could be fixed by minor changes to the protocol, like for example the minor changes of adopting SEP. They are very similar.

SEP is much more efficient, at least more efficient. Now, [with] efficiency I can't buy the cryptographic public [inaudible], they have public [inaudible] like decryption, and we have four of these compared to ten in STT, according to my count, which is about 2 1/2 times [the amount in SEP]. There is the licensing thing; STT requires licensing, certainly of RC4 which is a proprietary technology used in STT.

And we hear contradicting stories about whether licensing for Microsoft is required or not, and I really cannot say for sure that it is required. We never figured out that thing, but it may be required. We asked and got different replies on different occasions. And SEP does support the Web and e-mail, and STT is not able to e-mail, and there are differences of implementation.

So, to be very short, they are similar, and the differences are a closed versus an open approach. In the use of standards and interoperability, we work [with] all these vendors together so we really can make sure that there is interoperability. We have all the small details; this is very important, and that is something that has been shown in the Internet community many, many times. If you want a really useful interoperable standard you must have several vendors implementing it. In fact, you can't get a real Internet standard until you do have multiple vendors implementing. So it's a well-known lesson from the Internet.

[Now I want to talk about] efficiency and security, and the scope. So what are the steps that are included into the basic protocol? It includes [inaudible] on the certificate issue and in management, and implementation details over both Web and e-mail. This is how you interface to the financial networks, and there's quite a detailed error-handling and disaster recovery discussion. I'm not saying this is completely done and completely perfect and so on; quite on the contrary, this is still ongoing work. We are welcoming comments and criticism and so on, and there's an open mailing list to discuss these things.

The general overview of the system is probably something that most people cannot see. Okay, so we have the cardholder and the merchant which [does] the payment, and we talked to the acquirer, and on this cloud over here is a certification scheme that gets certificates to the different parties. I think most of you can see this, so you could make better of your time and questions.

Now, unfortunately you will not be able to read this [inaudible] also, and also I didn't even plan to present it. What happens is that I lost the high level of the presentation, but with this you can see the general flavor of the protocol. There are five messages in the interactive case of the protocol, followed by those that would be used in a non-interactive mode, which is fewer messages if interaction is for some reason not [possible].

And you see all these pieces of the protocol. Maybe I should give one example of the efficiency sayings in the protocol. People often wonder, how come STT is less efficient? Is Microsoft dumb or something? They are not dumb; I don't think that at all, and I highly respect these guys. Actually, we have many friends in their cryptographic group, so I would never want to give this impression. I respect them, but there are differences in the design of the protocol. It's not that the functionality is essentially the same, but there are differences in the [inaudible] of the protocol, and they are really the result of, I think, more tuning up that we have done — that's all, just more tuning up. So we've taken out some encryption of signature impression that were not needed, and all that could be replaced.

As an example, there is the signature by the merchant, the merchant in a sense wanting to sign, or to authenticate, two things. One is the initial offer that he's giving to the cardholder or is giving to the credit card system, because you want to be able to know that this really came from the merchant. So this is one authentication that you want. But then there's another one, where he wants to be able to authenticate that he got the payment, so essentially you want a receipt.

These are two different authentications, and it seems that you need two different signatures. But actually there's one long and old cryptographic trick in which you can say, "Okay, since I know in advance that they may want an additional signature, I can do it in only one signature operation." And the way is — do we see it here? So the way is that in the first signature you include also a positive, which is the hashing of a random number. And then when you want to change it into the second signature, when you want to give it another meaning, you just open the puzzle. So when you have a signature which stands for a specific puzzle and ends in an answer to this puzzle which only the merchant can give you, that means that you have a receipt. Without doing another cryptographic operation we got a receipt as well as a signature on the order.

So it's just a small cryptographic trick; not something very innovative, just a well-known trick. This whole protocol is not a traditional advance of cryptography work that we're doing; it's a very established cryptography that we're doing here, a very well-known thing that we could save a bit.

So that's what we try to do, we try to optimize because this will be [inaudible] many times, and I actually have it here. Well, I want to be able to do something with this scene; it's a competitor pull-up so I won't take it out, but this product, because it's a competitor's product — it's very weak, very weak computationally, and it takes a lot of time. So I really want to be able to minimize the time that it takes to do this shopping.

Okay, I want to leave some time for questions and you don't have too much time, so I will skip some of the more advanced things. If the questions will be there then we'll get to them.

So, just as a conclusion, I hope there will be convergence. I think that now the market should really focus on these two protocols, and it's not because I'm in one of these two

protocols. I think, realistically speaking, it's because I want convergence. That's why we began all these things. It's not cryptographically challenging work at all; it's simple work which traditionally we would not do even in my group, but we just wanted to have this convergence because it's important we're doing it, because we want convergence. Therefore I think we should focus on these two, and in fact we should put pressure on all involved to get convergence between these two themselves. [There's] no good reason why not.

There are some advantages, I believe, to SEP, which I say in spite of the fact that I'm involved in it. It's open, it's free, it is a broader scope and it has efficiency and security advantages. We are going to try to push these two to the ITF, the Internet standard body, to get open commerce and to try to converge into a standard. And for more information you could look at the MasterCard pages, where you can actually get all the specifications from these first [inaudible]. And these are two mailing lists. The first one is really for the discussion of that particular protocol, and the second one is what we're trying to establish with the ITF standardization forces in this area. I hope that it will be established soon as a working group, and then we'll start discussing this idea of a standard.

Okay, so thank you. Any questions?

M: STT and SEP, do they implement the new algorithm, or are they using RSA or what?

Amir Herzberg: They use RSA. If you mean public key, I wouldn't use RSA.

M: Another question regarding the newer channels you were talking about. Are they under discussion? And you were comparing them to [inaudible]. And do the applications we use need to have something done to them similar to peripheralizing?

Amir Herzberg: Okay, very good question. They don't necessarily need a key server. First of all, let's answer the second part. You don't need to do any change of application, so that's very simple. No, part of the idea is that you do it in [inaudible] and you don't have to change any applications. In fact, it is not necessarily even workstation software if you do it parallel to parallel. Okay, that's easy.

The other part about the question was, do you need a key distribution mechanism like [inaudible]? That depends. First of all, in the existing draft and the existing implementation we don't yet have the public key, so you need either to manually configure the public key to the endpoint, which is possible, and actually in many cases it's completely reasonable to do that.

If you think really about implementations in reality, then I think in many cases it's completely doable and reasonable, and for security we will actually change this key all the time, so it's not a security problem. The other thing you could do is actually use something — if you don't go to use the public key then you could use something like [inaudible], but just between these two things. So you could use [inaudible] or whatever is your key distribution, your favorite key distribution mechanism.

M: Are there any third-party encryption software packages available today? Something that you can buy and utilize to be in your application?

Amir Herzberg: I didn't completely understand what you mean.

M: If you want to buy an encryption software package, a utility so to speak...

Amir Herzberg: To encrypt what?

M: You encrypt whatever data you are transferring across the Web.

Amir Herzberg: Transferring in what way? If it is e-mail, then definitely there are packages. So you have to be very specific you know, [for me] to answer. There are packages that do some sort of encryption, definitely. In fact, as I said, there are even packages that do IP layer encryption in the market. But except for ours I'm not aware of any which is doing it in the standard way; that's the only difference which we are focusing on. Okay, there are, definitely, there are. Any more questions?

M: How specific is it to IP? If IP were to be replaced, and some other standard...

Amir Herzberg: It's not specific at all. I mean, there are some [inaudible] with the key management and most of the [inaudible], of course, are not specific. Some of the specific encapsulations are related to the fact that you encapsulate IP, but essentially there is very little signature-specific to this role. The key management definitely could be used in a completely different setting.

M: [inaudible]

Amir Herzberg: Well, when you do encapsulation you put it outside an IP header, so in the encapsulation there are some small differences relative to the fact that you encapsulate IP, definitely. You take the [inaudible] all kind of these things, but in most of the stuff it is independent.

M: Have you looked into using bar encryption in order to avoid export restriction?

Amir Herzberg: That does not help me, not at all. The only thing that would — you see, to avoid export, customers outside the United States should be able to buy the same product with the same encryption which somebody developed outside the United States. Unfortunately we cannot do this, not even by our subsidiaries outside the United States, because it has to be a company not owned by an American company. So while this is an excellent business opportunity, we have to miss it because of the existing export regulations. But other companies abroad can do it; they don't need a different encryption, they can implant the same encryption with no problem. Yes?

M: [inaudible]

Amir Herzberg: Absolutely, that's what I'm saying. I completely agree with you. In fact, that's what we believe and hope will happen, because we want to have our customers be able to do this. I mean, they need this, so that's one of the reasons you go to standard [inaudible] so your customer can buy this stuff. Yes?

M: [inaudible]

Amir Herzberg: Oh, that's a very good question, I apologize, yes. Any licenses except for RSA — that's definitely true, I apologize.

I just want to emphasize one other thing. Even with our existing product we do have an exportable version, and that version would still be very useful for security because it provides

authentication as well as a lower level of encryption. Authentication in many instances is what corporations really care about. If you look at this Berkeley [inaudible] for instance, what it's really done is [inaudible] the authentication. So it's still a very useful product outside the United States.

Yes, more questions?

Bill Washburn: What was the last question?

Amir Herzberg: Oh, it was really a comment. I said there are no licensing requirements, and the question/comment was, "Don't I need to use RSA, and isn't RSA licensed technology?" And the answer is yes, it was a mistake [on my part]. We do use RSA and you do need an RSA license.

Any more questions? So I guess we are done, thank you.

Mecklermedia

SPEAKERS

Peter Henry Stair

Senior Consultant, Mycroft Information

David Sachs

Assistant Dean, Pace University

Joel Maloff

President, The Maloff Company

Tristan Louis

Publisher, iWORLD

Bill Washburn: My name is Bill Washburn, and I appreciate your being here. This is going to be an interactive session. If you haven't seen the announcement to the change from what it was slated to be in the program, it's going to be an Internet Firing Line Session that will, as much as anything, to be perfectly blunt about it, rely on your asking tough questions.

I've tried to think of one or two, but I know that I really don't have the beginning of the kinds of serious commercial, financial and technical kinds of questions that you may well have. And so this is a session with respect to the opportunity to meet with people who work on the Internet, with the Internet, with businesses, with entrepreneurs, venture capitalists, large and small companies and the like, both in the U.S. and internationally, to ask about things that may otherwise never get answered or certainly receive attention.

So I urge you to — even as we are just beginning now — I urge you to write down the questions that you have. The reason I suggest that to you even now is because you will have more questions, or your questions may well evolve from one thing to another, and it perhaps is better to have all of them in front of you as you prepare yourself to ask the first question, which ought to be about now.

But please, as soon as possible, if any of you would like to turn it in I will be available down here in the audience, or certainly if you signal I would come down and get them, and then we won't know who you are.

Peter Henry Stair: When do you want us to introduce ourselves?

Bill Washburn: I'm going to get there right, just one second. I'm just trying to prepare the audience. You're prepared. The audience is unprepared in my estimation because I'm calling on you to really be participating.

Joel Maloff: It's an assumption that we're prepared.

David Sachs: Yeah.

Joel Maloff: We're aggressive.

Bill Washburn: That's a bad sign, isn't it? So before I allow... Is there a question? Two questions.

Yes, you in the back. No?

M: As soon as you're ready.

Bill Washburn: Okay. I'm ready.

M: Okay. In the general sense, which is more important, a [inaudible]?

Bill Washburn: Could we make a note of that question? Because I will take that question, but I would like to get the panelists introduced. Okay. Did you have a question before I get the panelists introduced? I would be happy to try and answer that.

W: It can wait.

Bill Washburn: Okay.

Joel Maloff: I have a feeling this is going to be an aggressive audience.

David Sachs: Yeah.

Bill Washburn: Good. Let's give you some red meat here, and we'll work on the rest later. I would like to introduce the three panelists that are acknowledged in the notice and also acknowledge, in particular, the president — well, not yet president — Tristan Louis, who was just recently promoted, in case you didn't get the first [inaudible] to be responsible for iWORLD at Mecklermedia. And rather than explain anything else about that, I will just say that he can say at most two minutes worth of things about Internet World origins of his and so on and so forth. I would like to ask each of the panelists to say hello to you and to give you further encouragement to ask questions and to be participatory.

So, ladies and gentlemen, we'll start with Pete Henry Stair, as listed, then David Sachs, then Joel Maloff and then Tristan Louis. And we'll go into questions within eight minutes.

By the way, one last thing; we'd like to do this in an hour so that you would have some time, so if you want to come and ask questions more informally and perhaps privately — I don't know why you would want to ask private questions, but I'm sure there might be a few reasons that you can think of, and also in case you want to get into the exhibit hall one last moment.

So Pete.

Peter Henry Stair: Bill, thank you very much. My name is Henry Stair. You can call me Pete. Please don't call me Hank. And please call me for lunch. I work for a company called Mycroft Information Internet Consultants and Telecommunication Consultants, and like [Durgan Park] I've probably been in business since before most of you were born.

David Sachs: Hi, I'm David Sachs. I teach at Pace University in New York. I write about the Internet a lot and teach about it a lot, and I'm happy to be here.

Joel Maloff: Hello, my name is Joel Maloff. I am a Internet consultant, primarily for businesses. I've been involved in the Internet for about ten years as executive director of the Big Ten University's Research Network, as Vice President of Sales and Marketing for ANS — Advanced Network and Services — and for the past two years as an independent consultant working directly with businesses to try to help them understand how to use the Internet as a business

tool, to reduce expense, to increase revenue and to benefit their bottom line.

I have a book called *Net.Profits* that's just come out. And I do work all over the world with corporations ranging from the Toro Company, Metropolitan Life Insurance, Nationwide Life Insurance, CompuServe, MCI, IBM and so forth. So I'll be happy to answer any of your questions that you may have.

Tristan Louis: Hi, I'm Tristan Louis, publisher of iWORLD. For those of you who are not familiar with iWORLD, it's Mecklermedia's Web site, which has been totally redesigned, and you can see the new look over there on your screen. Before that, I have been jumping around a lot. Even though I'm probably the youngest panelist here, I've been in the Internet for about eight years, and was really one of the pioneers on the Web since I was one of the people instrumental to setting out the Sun site at UNC, which for those of you who are familiar with the Web was one of the first fifty Web sites.

Bill Washburn: Say the long name of UNC.

Tristan Louis: UNC is the University of North Carolina at Chapel Hill, and for those of you who are not familiar with it one of the hot centers for Web development.

Bill Washburn: Okay.

Joel Maloff: Actually, I want to add that he does not have a North Carolina accent. He also doesn't fit the rest of us and he's not part of the "Internet Bearded Guys Society."

Bill Washburn: Okay. The question that was asked already, "Which is more important, time to market or..."

Joel Maloff: Functionality.

Bill Washburn: Functionality.

Peter Henry Stair: Let me assume we're talking about a service, or product or program, and the question then is are you willing to take the risk of crash and burn early on and become a footnote to history by having clear functionality or insufficient functionality just to get it out there, or are you better off to be the second or third entry into the market? It depends a lot on who your competitors are, the speed of their response and how far ahead you are or far behind you are.

Joel Maloff: I would also add that I think it's critical that any time you move into a business — and that's what it is — you consider these as nothing more than business tools. It's important to identify who your competitors are, what customers are looking for, what the product needs to do, what the price performance is going to be. All of those issues need to be considered up front.

I agree with what Pete said — if you have a product that doesn't meet the needs of the market, but it's there, it's not going to sell. If you open up a Web site and nobody knows it's there, it's not going to sell. You simply need to consider this as part of the normal business process. You need to do a business case analysis. You do not need to do paralysis by analysis, but you really do need to know where you are going. There's an old saying: "If you don't know where you're going, any road will take you there."

David Sachs: Yeah, I would also add to that. What you're watching is companies that are doing a layered approach, if you will, because it's probably a good way of hedging bets. Fidelity is a good example of that. At the moment there are no transactions that can be completed using that particular network, but it's there as a way of providing information. So maybe you can come back and look at your own question and say: "If we were going to roll this out over a year, where is my 100% of what I want, and is there a way to incrementally do some of what I'm heading towards in a well-designed way?"

So maybe instead of a black or white fallacy that asks, "does it have to be time to market versus functionality," maybe a different answer says, "maybe there's three or four, if you will, target points that I can head towards, and maybe I can do a good job of each one of them, but I don't have to do all of them tomorrow."

And in fact, what you're watching is a fair number of companies that are saying: "I'm not sure just yet what I want to do, or more importantly why I want to do it, but I want to be there doing something well." So therefore you pick minimal risks, minimal costs in terms of time and technology and all the rest of it. You do it well, it's there and then you come back and start to say: "Okay, now what do I know, and where do I want to go next with that?"

Tristan Louis: I'm going to take the radical approach here by saying that they are not mutually exclusive. Most of the twenty-something generation — my generation — is very impatient, and it fits very well in the Internet model. As a result you can bring the product to market very quickly and still make it very functional.

Now, there's only one prerogative in this — lack of sleep. The people my age, are usually — in this industry — are usually putting in 20, 22-hour days, bringing the product to market before anybody else, and then the big companies turn around and look at us and go: "Wait a minute. Why did you come up with this?"

"Well, we've been working for the past three months on a product, but we probably put as much time into this product as you would over the course of a year or two."

Peter Henry Stair: Us old guys work a lot of hours, too.

Bill Washburn: This could be bragging and complaining here, I think. First here, and then...

M: I have an open-ended question.

Bill Washburn: Could you stand up and speak so the whole audience could hear as well?

Joel Maloff: Bill, maybe you could have him hold the mic.

Bill Washburn: I don't know if it will reach.

Joel Maloff: Yeah, we've got a long cord right here.

M: This is an open-ended question regarding what I thought we were here for, commerce business-to-business transactions. What are the critical factors to success? Who's going to be able to carve out either a large market share or a niche, whether it's Open World or any of the other players? Just some of your thoughts, both from the short term — six months to a year — and the medium term.

Joel Maloff: Are you referring to the Internet services like Netscape or Open Market or otherwise, or are you talking about the end-users?

M: I'm talking about who's going to be able to facilitate business-to-business transactions over the Internet, if it is Open World, with a bank or something like that?

Peter Henry Stair: Really, back to the original topic of secure transactions. Okay, critical factors: I suspect we can draw a parallel here with early aviation. If we get a lot of headlines about a lot of crashes and a lot of deaths and a lot of mangled corporations, we're probably going to set the Internet back. I think the flurry that was caused by that rather minor bug in *Netscape* a few weeks ago is an indication of a press — my apologies to the press who are here — ready to pounce.

Bill Washburn: [The] press aren't here, so you can say it all.

Peter Henry Stair: Right. Well, I think your first critical factor has to be the nature of it. We have to be pretty sure that our security is awfully good. Because one corporation burned, and the publicity about it, could set this whole commercial field back significantly.

Joel Maloff: What's interesting is that as I look at the development of the commercial Internet, including transactions, the total commercial Internet is only five years old. The WorldWide Web has been around less than three years, and Netscape is less than two years old.

I look at Open Market. I look at SSL. I look at all of the different projects that are underway. We're still in the very early stages of this kind of development. With the huge growth of end-users and businesses now beginning to look to use the Internet, there's an enormous amount of stimulation and money being spent on developing secure approaches and secure technologies. I think we are in a position today to be able to do — if we are willing to pay for it — secure transactions. Now, that may mean that we've got to make it iron-clad. It may mean that we have to use not only secure socket layer or SHTTP or some of the other devices, we may have to couple that with physical authentication devices like smart cards or biometric scanners. It can be done. The point is identifying the business issues involved. Who are we protecting these transactions from, how much is it worth to us to protect it? We have the ability to do it. We are getting better and better at it, and we need to keep in mind that we're still very early on in the cycle of this industry.

Tristan Louis: One of the things that worries me is people always complaining about the lack of Internet security. But what few people realize is that the Internet is actually more secure for commerce right now than the telephone is. People don't think twice before giving their credit card [number] over the telephone; yet some hacker can be standing behind your phone line with a cellular phone and pick up whatever you're saying on it. Nobody pays attention to that. Everybody's screaming: "No Internet! Commerce is not possible because there's no proper security!" I'm sorry. I don't see where the point is.

M: This week we saw Oracle go out on kind of a bold move to do some different things. Do you guys think the Oracle approach is going to work, or is there a difference? Is it kind of a tradeoff between Oracle and Netscape as far as the Web is concerned?

Peter Henry Stair: Are you familiar with the Oracle?

Joel Maloff: I'm not familiar with the Oracle. Are you familiar with it?

Tristan Louis: Somewhat.

Bill Washburn: Go, go...

Joel Maloff: Well, I'm not, so why don't you start? And then I've got a general comment.

Tristan Louis: Oracle has been making some interesting comments left and right. My main question is, when is the product coming out?

Bill Washburn: Tristan, you characterize.

Tristan Louis: Yeah, essentially what happens is that on Monday Oracle announced a bold new approach with *Websystem*, which will allow its proprietary browser to access Oracle databases. They've been talking left and right. Sybase is currently doing the same kind of development, though they don't have the same marketing pull as Oracle does. And what Oracle is doing right now, in my view, is its positioning itself. They've been spending lots of money on set-top boxes, figuring that the information superhighway would happen with your television, and now they realize that their investment in this is pretty much lost. So they are trying to make up for lost time by making a lot of announcements. The question is when is it, where is the product?

Netscape, on the other hand, already has a product on the market. And I think Netscape's approach is very different than Oracle's. Oracle wants to essentially go through and deliver content through databases. Netscape says: "Okay, fine. We'll let you do that and we'll let you hook up to our servers. We'll also provide the front end, as well as providing the operating tools." What Netscape is doing is essentially creating a link between your browser, your authoring tools and your Web server. They are covering all of the bases. What Oracle is doing, on the other hand, is just covering the back end of the system.

Joel Maloff: From my standpoint as a consultant, I want to see as many different approaches as possible. What is of concern to me is that I want to make sure that they are open approaches. As an example, if I have a client that's looking to do electronic commerce, I want them to be able to accept money in any way anybody wants to spend it, just as if I go into a restaurant, I want to make sure the restaurant takes American Express or VISA or Discover. Same thing with the new approaches that we're seeing here. I want to see open standards, and I want to give my clients as many ways as possible to make money on the Network. And so the issue of closed approaches concerns me. I don't want to see an SNA environment as was in the past, where an SNA Network doesn't talk to a DecNet Network and so forth. I want to see open systems, and that to me is the underlying beauty of what has made the Internet successful in what it is today, and I want to see that continued.

Peter Henry Stair: Let me second that, Joel, and point out that some of the things we've seen here this week — particularly in the case of CompuServe, America Online and Prodigy — have been announcements that they are moving away from, or at least in addition to their proprietary client software, moving towards also open software featuring fully open Web access. So the market is moving us in that open direction. There may be additional pushes for proprietary or closed systems; I don't think they're going to happen. Personally, I think you're going to find that they will be rolled over by the open systems.

Joel Maloff: Somehow I don't think AOL, Prodigy and CompuServe were doing it to be benevolent, either.

Tristan Louis: Correct. There is that fact. And there is also the fact that Microsoft is trying to push a more proprietary approach with *Blackbird*. I don't know how many of you are familiar with it; it's a new authoring platform. What I fear is that some time in the next six months, when *Blackbird* come out, it's going to be essentially a match between Microsoft and Netscape as to who owns the authoring platform. All of them are trying to push their own standards, saying they are open standards, when they're not really, and that is very worrisome.

Bill Washburn: Why don't we wait for another question?

[Sandra Woodruff]: I'm Sandra Woodruff from the Happy Puppy Games On-Ramp. We've kind of reached a point in our evolution where — this is probably a very specific technical question — but it's a problem for us. We have server sites in Washington, D.C., Chicago, and soon in Seattle. And unfortunately, the Internet doesn't seem to have made any arrangements, so we keep having to come up with new domain names. And I'm wondering is there a technology available, some higher level of whatever addresses so we don't have to keep coming up with new names, so that people can actually find us in one easy spot?

Bill Washburn: You mean to say new as in additional, or new as you change away from what you have?

[Sandra Woodruff]: Additional. Yeah, we're happypuppy.com and we're happypuppy.net. And we're starting to run out of combinations.

Peter Henry Stair: I'm not sure I understand the question. Are looking for a way to be able to extend or cover various machinations of that?

Joel Maloff: You're looking at, I think, at this limitation in the common domain.

[Sandra Woodruff]: Well, the problem isn't that so much as that we find that we can't do business on just one server because of the bottlenecks that keep cropping up in the East and stuff, and so we've got to open more servers, and we're probably going to be opening more across the country yet as things get busier. And it's the only way people can get through to us, because we've got a pretty good gob of business coming in now.

Peter Henry Stair: So what you're really after...

[Sandra Woodruff]: Where do we go?

Peter Henry Stair: Is there one domain that can point somehow in a load-balancing fashion in multiple servers?

[Sandra Woodruff]: Right.

Tristan Louis: From a technical point of view it is actually doable. It's not a cheap option. You're going to have to essentially create your private Internet. By that, I mean you're going to have to link from one machine to the next, and essentially create a mini-network using TCP/IP stacks

and connect each of those sites to main points on the Internet. And once you've created that private Internet you can actually redistribute your content from one site to the next from the same IP. The only problem with this is that there are some serious security holes.

Joel Maloff: [inaudible]

Tristan Louis: Joel was asking me, how does that compare to mirroring a site? Well, the advantage over a mirroring a site is that you have only one IP address instead of having several, and therefore you can point to that IP address, and when it checks into the DNS it goes to your main server, which redistributes that across your private Network.

Bill Washburn: Okay. Back there and then here.

W: [inaudible]

Joel Maloff: The question was, in the case of a small company that's looking to set up a Web site, what skill set are you looking for in a project manager?

W: Right, from a technical standpoint.

Joel Maloff: From a technical standpoint. First point on that is that this is something I get involved with a lot with clients, really all sizes. The first thing that you need to do is, from a business perspective, decide what are you trying to do with this. As a site, are you trying to use it to create image to generate leads, to close business right there on the spot? That helps you understand what kind of resources you need. You then have the ability to create a request for proposals, find outsource partners who will do that for you. Internally, you're going to need someone who has the ability to maintain your content. The outsource provider doesn't do that. The person who is going to be maintaining the content will have to have the ability, understand how to be able to FTP new information, how to be able to log into a staging server, and to update that information and work with it.

From the standpoint of some of the clients that I've worked with, that person does not have to be overly technical. They can be — call it a sophisticated corporate librarian — and work in a coordinating fashion. The outsource vendor can do much of the detail work for you.

Peter Henry Stair: Now, let me add to that if I may. The content provider also, in addition to just skills, needs to be tightly linked with the rest of your media people, artistic creative people, so that they're not off on their own. One of the risks that I see a lot of my clients getting into is they hire a very technical person. The technical person goes into a closet and does a wonderful Web job, which has absolutely no relation to the campaign of the rest of the company.

David Sachs: You wanted to clarify the question.

W: Yeah, my concern is really in evaluation of new technologies. For example, the transaction presentation that [inaudible] plays is fairly high level. Someone who's not been involved in programming, and was wondering how one could evaluate those issues without being...

David Sachs: But you have to decide where your technology is going to reside, right?

W: Right.

David Sachs: And you have to decide why you've got to do it all. Or in other words, it's the classic: "Do I build, do I buy, do I rent, do I lease?" It may be that you're looking for a superman/woman who's going to know everything that you need to know, and maybe you're working too hard. I mean, I don't know anything about the size of your business, the scope of your business or what you're doing, but I would come back to Joel's point that first says, you know: "What are your goals? What are your objectives? What's your business plan? Do you need to own all of this technology expertise internally, or can you give some of it away?"

And in the process, then, you're better prepared to focus on what you really know how to do. And maybe — because it sounds like you're trying to find one person who's going to be able to do everything — that's not realistic, either. So I think there's more questions to be asked. It's not that you might not want to have technical expertise there, but it's clearly growing in leaps and bounds, and it may be that one person is not the right answer at this point. You've got good Internet presence providers who might be able to do the technical side of it, and then your issue with them says, "Talk to me about the strengths and weaknesses of a different approach," not, "I've got to know everything and sort it all out myself and solve it all myself."

Joel Maloff: Let me add to that, too. And this is going to sound somewhat self-serving, but that's what you hire consultants for.

David Sachs: Well, that wasn't self-serving at all. What do you do for a living, Joel?

Joel Maloff: Oh, consulting.

The point is that many companies are outsourcing these kinds of skills because it's hard to find these people that understand it. And it may in the long run be a lot less expensive to bring someone in who is a good project manager, understands your business, understands what you're doing, and you bring in someone like one of us on the panel for a day or an hour or whatever it may be, and say, "Okay. This is what we've thought of. Blow holes in it. Tell us where it doesn't work. Tell us what we need to do differently." That may work a lot more effectively than trying to find that perfect person at the place that you can afford if you're a small company.

Tristan Louis: I know I'm going to get shot for this by the three consultants on this panel, but there's actually a lot of college students right now that have the knowledge that...

Joel Maloff: Yeah, but not the experience.

Tristan Louis: Maybe not the experience, but that have the knowledge of this industry and can essentially recommend certain options, and help you out in making your decision.

Peter Henry Stair: Be cautious, however. If I can counter Tristan here, be a little cautious in this area. Unless you happen to be related to them or they're slaves, they will tend to gain much experience while working for you and unless you have very, very strong employee benefits programs they may look elsewhere.

Joel Maloff: Yeah, and I think it's important to understand that, as Tristan implies, this is where the Internet has come from. It is not where it's going. You're going to a professional environment where you have people that understand business. They understand how to ask the right questions rather than coming in saying, "Cool. Neat site."

Tristan Louis: [inaudible]

Joel Maloff: No, no. You don't get a chance to rebut me on that one.

M: That's actually a nice introduction to my question. As the Internet commercializes and as Netscape introduces their own semi-standard proprietary standards, et cetera, et cetera, are organizations like IATF going to be able to keep up? Who's going to help approve standards? And even if they do approve them, is everybody else going to pay attention?

Tristan Louis: Well, my question is, are there any standards left? The WorldWide Web consortium is jumping left and right saying, "Netscape, HTML 2.0 is still the one to run, HTML 3.0 hasn't been approved. You can't use a center tag. You can't use a table tag. You can't use a background tag. Look at the use on the Web; I mean, let's get real. Netscape has taken over the market with proprietary tags, and a lot of browsers are actually including those tags within the browser to support it. I think standards at this point are pretty much dead, left in the water. The committees are essentially going to give their approval on standards, but they will be implemented long before they're approved.

Peter Henry Stair: You know, I think what we're actually seeing here is we have a new standard as we commercialize and that standard is called the market. Where is the market going? Where are we going? 24 months ago, *Mosaic* came out. *Netscape* hadn't been born yet, and now 80% of us — according to statistics — use *Netscape*. That's the standard today. I don't know what the standard will be tomorrow, but I agree with Tristan that the standards groups will become recording bodies of the movement of the market.

Joel Maloff: You know, it's interesting, we talk about Internet standards; we don't have standards, we have RFCs, and they are "request for comments." When people stop commenting, they're sort of standard. We don't have standards in the same way that [CCITT] or other standard-setting bodies do.

It's important to remember that the Internet is not a technical entity. It is a community that only works together because everybody agrees to operate in a certain way, and it is that and market forces that will drive this together. I think the IATF, to get back to the question, will continue to exist. There are needs for it. I believe that many of the spin-off groups, the security group, the end-user group, the information services groups, all have done great work, and what it does is take advantage of the fact that we are a community rather than a technical entity, and that's where a lot of the development comes out. Netscape participates in these. So do the various security vendors. And sure, there are competitive issues going on, and market forces, but the embryo, the equivalent of the research and development that goes on in Japan, in the Internet, is occurring in these task forces.

David Sachs: And could I just add one more quick comment? It's also interesting, if you spend a lot of time looking at, for example, a given browser... Pete and I just finished working on a book called *Hands on Netscape*. Now, six months ago Netscape did a certain number of things, and you could pretty much talk about the traditional, if you will, Web activities that it did. Suddenly today, Netscape still does a certain number of things, but suddenly if you wander downstairs, there's this *PowerPack 1.0* that's available. Suddenly you've got a Netscape that includes real audio. You've got a Netscape that's going to include Apple *QuickTime*. You've got a Netscape that's going to include more and more corollary products, if you will, so what are we

really using anymore?

In other words, I've got *Netscape* that does a certain number of things. Yes, there are standards. That's terrific. But by the way, if we could show a class this morning, here's an example of *Java*; who in this room was thinking about *Java* six months or a year ago? And suddenly you can't walk on the floor without [seeing it] Maybe six months ago, certainly not a year ago.

But you suddenly look at the timeline and you say: "Isn't it interesting? We're talking about a browser that does a certain array of activities, but you've suddenly got a whole potential for a whole group of other things, and in a funny way that's become a standard that others are going to have to pay attention to. Whether it's formalized or not is almost not the issue. But if the browser I've got on my machine can give me real audio, I've got sound in real-time. It can give me movies when I choose to have it. It's going to potentially let me access with *Hot Java* something beyond that. Suddenly the platform has moved. Whether or not it's certified by anybody on the planet is almost irrelevant, but the platform is there, and you've got whatever, ten million people using it. Well, that sets a certain tone that I think you have to attend to.

Tristan Louis: I want to also be somewhat more cautious.

David Sachs: But this poor gentlemen is trying to get a word in edgewise here.

M: I agree with many things the panel has said, [inaudible] at the same time. Unfortunately, it's no longer an organization of university students and professors and knowledgeable people. Now in businesses you want to make a profit, which is great. And [inaudible].

Tristan Louis: That, that...

M: A desire for open systems that Joel mentioned earlier, and the fact that you want all this stuff. That's just a hard balance.

Tristan Louis: One of the way I'm looking at this essentially is what tags have been submitted to the committee standards and are being seriously considered by the committee standards. I mean, I'm not waiting for the approval when I am thinking of designing a Page, I'm just looking at are they actually talking about it, will they eventually approve it in one way or another? And you have to be very careful in adopting those tags. While the market does dictate to some point what you're going to use, you have to also be very careful because a year ago, we hadn't heard of *Netscape*. Who knows what will be the hot browser a year from now?

Joel Maloff: My feeling is that the market is the driver. I mean, the market is the bottom-line judge.

Bill Washburn: Next question.

M: Yeah, hi. I work for a financial services institution, and right now we're trying to evaluate different micro-payment solutions, different electronic money schemes, and one of you, or maybe many of you said that consumers are willing to pay for secure solutions. In micro-payments, how do you — do you understand that?

Joel Maloff: By micro-payments, you're talking about a penny or two a transaction?

M: Right. Anywhere under \$5. People like Digicash, people like that.

Joel Maloff: There are a variety of ways that those are being addressed. Actually, when I work with my clients, if they're looking at very small payments... As an example, I was involved from the very ground up with the Discovery Channel site, and one of the areas that we were interested in is that perhaps we [might] want to charge for recipes. Someone has seen a cooking program, and they want to download the recipe, and we're going to charge a quarter, 25¢ for it. [That's] the way we've approached that. And again, we start out with business approaches rather than technical approaches.

The first business approach is essentially you have a subscription. You know, it's a dollar a month, and you can download up to four 25¢ recipes for that. And you keep essentially renewing it. It's almost like the long-distance card; you renew how much you have. Nobody is going to want to put a 25¢ cent charge on a credit card. It's ridiculous, so you're not going to do that. I know there are some technical approaches that are being considered, but for right now the ones I recommend are managerial approaches. I don't know if anyone else on the panel wants to address this.

M: The other part of that is [inaudible].

Peter Henry Stair: Let me try to tackle that. The model that Joel's presenting here, a business model, is the correct approach rather than the technical approach. It's not clear that if we look at ourselves as users, that I'm prepared to carry another form of money just yet — an e-cash of some form, whether it's in electrons of some card. It's not clear that I'm prepared to pay micro-charges. It is clear that I'm prepared to accept a certain amount of advertising. It is clear that I'm prepared to have very few subscriptions, but I'm not sure that we're going to get to a point where we're going to be able to sign somebody up for micro-charge subscriptions.

I think, again, that the market is going to have to lead us there. I'm not, at this point in time, smart enough to tell us which way we're going. As it evolves over the next year or so we may see some leaders in this area. I don't know how well e-cash is doing now that it's out, but I suspect we're going to again see what the leader will become. I don't know what that leader is.

Tristan Louis: The Copyright Clearance Center yesterday made an interesting announcement with IBM, where they're essentially going to try to attach some kind of payment identification to any piece of work that goes over the Internet. This [may be] another standard company trying to push their own thing, I'm not sure how well this is going to work.

For micro-payment to work, in my view, it will have to be included in the browser. Essentially what will happen is that you will receive a bill, much like your cable bill right now, where if you pay for a pay-per-view movie, you've got an extra charge on your pay-per-view bill. You will receive a bill from your provider, and all the payment will actually happen on the back end, where your provider will pay back those content providers.

David Sachs: It seems today the closest I've seen... I don't know how many of you are familiar with InfoSeek? Well, I mean, they've got a model that basically says I can do a search for a dime a piece, only in effect I register to do a hundred of them a month, and I register with my credit card once, and it's \$9.95. And then I do my 100 searches, and it's 10¢ for each additional. Either that — and they actually break it down even smaller than that. I think you can do it for, last time I looked, either \$2, \$5 or \$10. So clearly the unit of measurement is still somewhat bigger than a quarter.

But in effect, what they're saying is okay, if you want to commit to \$2 a month, you're going to be able to do whatever it is, ten searches. I think \$5 was like thirty or whatever. So they're clearly chipping away at it. And the other approach is probably going to be, do you get some extra bills added to your Internet service provider at the end of each month?

M: I'm a vendor. I have research reports that I do that are available on my Web site. People can download them. I've [been] thinking about the prospect of having every Internet access provider having to collect money for things that I've done, and that really is frightening to me. I want the money to come to me. Not that I'm greedy, but I do not like middlemen. And I think we need to come up with ways where the vendors are in control of the money. The more and more layers that we implement, whether they be technical, managerial or otherwise, means somebody's going to be taking a piece of my money, and I'm not interested in that.

Bill Washburn: Next question.

M: I too am a consultant, and a comment to your comment before, which is that I think consultants should be hired to tell a customer how to put the team together to build the thing. And the first thing he should do — or last thing he should do, but certainly must do — is pick the manager.

Joel Maloff: Yes.

M: Or help pick the manager, because that's the key. My question is, like the mass mailer's attempt to beat the race to the trash basket, how do I get the browsers to go to my site, and must I allow them to consummate a transaction when they're there in order to have them satisfied for having been there? Those are my two questions.

Joel Maloff: I'm not sure I understand about being satisfied.

M: Enough to come back.

Joel Maloff: Oh, okay. Got it. I understand. Couple things. First of all, let me see if I'm clear on the question. You want to know how you get people to come there, and how do you get them to stay?

Okay. From a design standpoint, it's very important to recognize that a Web site cannot be an electronic billboard. You can't scan in a brochure and just think that that's going to work. It's boring. It has to be interesting and it has to be interactive.

So the first thing that I tell people is that if you're going to create an Internet site, you need to tell people that it's there. You do that by using your existing physical media for communication. You have a newsletter. You have invoices. Make sure it's on everything. Then you identify — using the search tools — the neighborhoods in cyberspace where people are that are interested in you. The newsgroups, the list servers. You monitor them for a while, lurk a little bit. When the opportunity is right, you post a message and say: "Interesting you asked that, come visit us at www.widget.com." Invite people to come in. Once they're there, then the trick [is] to keep them there, keeping it interactive, and making sure that you have a relatively minimum amount of information on the page. I don't believe in scrolling; if I have to scroll down on the page and read more than a page of words, I ain't coming back and I'm not reading it. I like lots of clickable images but in small bites.

One final comment. As I mentioned, the Discovery Channel is one of my clients and it's

been very interesting. Discovery is obviously a media company. They are the only cable TV channel that has 100% cable penetration in households anywhere in the world. Every cable system picks up Discovery. In doing their site, they do it like their magazine. They have had to go out and find journalists to work on the content and re-train them in how to write in small bits and bites, and I don't mean that in computer terms, just small units of information, because people don't read full pages. So it's an entirely new journalistic style that is now being used in that environment, and that works. They're getting about half a million hits a day on that site. It's one of the most popular sites on the Net.

Peter Henry Stair: Let me point to a couple of other things that move away from our classical sort of print or television media. There are companies who are sponsoring, shall we say, a community benefit. They're putting something on their page that draws an audience to them. And the one I'm thinking of in particular is Maxwell Laboratories and the Los Angeles freeway speeds. I don't know of anyone in Los Angeles these days with a car who doesn't refer to that page at least twice a day. What is it? It's simply every two minutes exactly what the traffic is on every freeway in Los Angeles, in a very simple, graphical form. And every time you look at it, you get hit in the eye with a Maxwell Laboratories page. Well, lovely. One of these days, a few people may actually look a little further there. But they're sponsoring something that is of use to the community. This is the old Internet image of give back to the Net, and in the process then perhaps I can promote my company.

So there are more new models coming along than we've seen in the past, and some live or useful or fun information adds value to your page in certain ways that brings people there in the first place. Freshness, as Joel has mentioned already, brings them back. You want them to bookmark you, and you want them to come back regularly.

Tristan Louis: What I'd like to say is that essentially *USA Today* led the way to the Web. *USA Today* has proven that yes, you can do stories in one single column, with maybe one jump per section and a 500-word story, tops. And a lot of members of my generation coming out of the current journalism schools are using the *USA Today* model as far as writing is concerned, to write on the Web.

David Sachs: But I would also... I guess I have two perspectives. Certainly, one is to be attentive to numbers of words on pages. But I think that really begs a whole series of questions. I know that I go to places in my life that provide me with either valuable resources that I want or useful information that I'm looking for, or a set of tools that somehow serve a broader purpose or an answer to a question that I've got. And it seems to me that when I find that I'm less concerned at that point about did it take — I mean, with all due respect to other opinions about length of words and all the rest of it, I grew up in a generation that used to read, and we used to actually read books. And I'm convinced that when we encounter things that are of interest to us we read more than five hundred words, and I'm convinced that when we find things that we want we will spend lots of time there.

And so I think the broader question, and probably the underlying one, says "What is this site all about?" In other words, I have tools on my computer or tools on my browser that we call bookmarks or hot lists or whatever. If I want information I can quickly go to two or three places that get me that information. If I want research done, I've got places to go get it. If I've got weather information... So it seems to me before you start to talk about the length of it and how pretty it is and whether it's got the graphics and all the rest of it, is it useful? Is it valuable? Does it serve a purpose? Does it enhance my professional life? And if the answers to that are "Yes," then I'm going to go there and I don't care who provides it at that point. I'm going to go

because it serves the particular purpose I've got. If, in the process, I get to read some advertising, or if in the process I get to learn about a company that I didn't know about...

If I lived in Los Angeles I'm going to go to that L.A. Freeway Speeds Page, and it's nice that it's Maxwell Laboratories, but I was interested initially in the L.A. Freeway Speed not Maxwell Laboratories. So I think there's a different set of questions you need to think about.

Joel Maloff: A very quick comment on that. I saw a statistic a couple weeks ago that said that by the end of this year, 20% of Web sites were expected to be profitable. What does that mean? How many of them are trying to be? I think it's important to recognize that many of the sites that are out there are out there for image only. I mean, is the traffic site going to be profitable? Probably not. But again, you need to know why is it there in the first place, because if you don't know what you're trying to accomplish I assure you that you will be disappointed.

M: I have a general feel question. We've been developing Web sites for quite a while. We were one of the first fifty on the Net. The [inaudible] Community College. And now we've gone commercial, and a few of us have spun off and started businesses. We've been fighting the urge to go to Netscape pages. We've been fighting tables. We've been fighting — not fighting it actively, but resisting going on true Netscape. It's very apparent to me that going around the show floor and seeing Netscape with Live Wire, Live Wire Pro, 2.0 Frames, et cetera, and they're just eons ahead of everybody else. There's Netscape, then the rest of the crowd. And now I have talked to Prodigy, and Prodigy says that they've formed an agreement with Netscape and they'll be included with...

W: [inaudible]

M: Yeah. They'll be doing Netscape on Prodigy. So now I'm going to probably go back home and say, "Okay, let's all dive into Netscape from now on and go pure Netscape." I wanted to get your feel on that. My real question is, who's going to win this thing? You've also got Microsoft now with proprietary this and proprietary that, and "Oh, it's fantastic. You can have Word on the Internet." Wonderful. You know, you can have Blackbird on the Internet. Great. Where's the rest of it? I think from the middle we have a problem that the standards committee, the Internet IATF and RFCs were built for a community that wanted to cooperate. You don't have this any longer. Microsoft has no desire to cooperate with Netscape or else they would have built a Netscape-compatible browser, And Netscape certainly doesn't want to cooperate with Microsoft. And so I really see the whole thing kind of potentially crashing down and having fifty different browser types when you hit a site, which is going to kill Web developers like us.

So I kind of wanted to get your feel on what do you think is going to happen with, who's won? It seems to me Netscape has won. You've got the Microsoft threat that could come out. I haven't seen the world embracing the Internet Explorer, nor MSN. So I kind of wanted just to get the panel feel on who's going to win and what's going to go on? Should we go Netscape, or forget it?

Peter Henry Stair: Okay. Let me start this and then I'm sure all the rest of us may have an opinion on this.

Joel Maloff: Never.

David Sachs: No, we don't.

Peter Henry Stair: The winner, I think, is maybe not exactly the question. I'll go back to one of Joel's original comments. If I'm developing Web sites I want to make sure that whoever my constituents are — they may be my business partners, customers, whatever — I want to be able to make sure that they can see what I want them to see. If they happen to be 90% Netscape, then I'll go Netscape. If most of them are on America Online, then I want to make sure they look good on *The Other World* browser. If I want to look good to everybody, then I'll start with links. Because the people who are looking at my site may be overseas and running off 2400 baud modems, and they'll be using text [inaudible]. So it's almost a race where Netscape can claim they've won, but it isn't entirely clear what they've won. It's tough to say you're a 90% leader in a giveaway market.

David Sachs: The race isn't over, either.

M: I'd suggest we're not in a 30-yard dash.

David Sachs: Well, and I would also give you a couple of examples to look at. Bell Atlantic, I believe, has an interesting page. When you get there you're asked to make a choice. And right off the bat — and they way they say it is in wonderfully glowing, positive terms — they say: "If you have a high speed connection, then select this choice, and you'll get to see lots and lots of graphics," etc., etc. And they say: "If you would like the quickest possible response time, then select this second choice." Well, what they're really saying with the second one is that if you have a lower-speed modem or a dial-up connection, then make the second choice.

Now, I think at some point that question could just as easily be three or four questions, and we now have technology in place that will identify, before you ever answer the question, what kind of browser you showed up with. So it may be that before you get done you're going to have to use both the technology to identify that, and maybe people are going to have to make a choice.

And again, then what you say is that you've identified who your potential audience is, you've given them a chance to participate in that discussion. You know, if I [have] all kinds of time on my hands and I want to look at graphics slowly over a dial-up modem, I may choose to do that. And maybe I don't want somebody telling me which browser I have to use. Maybe I want to change every month, but I want to get to your given site and I want you to be saying to me, "Gee, we've done a survey. There are three or four browsers out there that people are using. Select a box and go from there and have a nice day."

M: Then what happens is that we'll have not four browsers, but we'll have twenty.

David Sachs: Right.

M: And Apple's browser...

David Sachs: Right.

M: [inaudible]

David Sachs: And there is clearly a change. Yeah, sure you get to a site with Adobe portable document format and all of a sudden you go to the *New York Times* — that's a real good example of finessing the whole browser issue — and it says: "But, by the way..."

It also makes it so easy for me. The first time I got there I downloaded Adobe Acrobat

Reader, and now I can do what I need to do there. So probably all of us are going to get watch this shootout occur, and whether it's over a hundred yard dash or a marathon is not the issue. And the question is going to be: "Do you give me the ability when I get there to do what I thought I wanted to do before I got there, or are you going to turn me away at the door because I don't have your given browser?"

I would submit that if somebody did that to me I'd leave and not come back. But if they make it easy for me to participate, like the *New York Times* did, I'm a happy camper on two scores. Now I've got new software that I didn't have before, and more importantly now I've got access to a service that I thought I wanted to get to.

M: So now you've got to load the Adobe helper, the Microsoft *Word* reader...

David Sachs: Maybe so.

M: The, you know, *Blackbird* reader...

David Sachs: Right.

M: And probably not with *Netscape 3.0*.

Tristan Louis: Yeah, *Netscape 3.0* will be about ten megs. Actually, I think your question is, who's going to win this war? In my view, the users are going to win it.

Peter Henry Stair: But who's the developer?

Tristan Louis: From a developer's point of view, you just have to make sure that you adapt to those changes. If tomorrow morning Microsoft *Explorer* comes out on top and leads 80% of the market, well, you're going to spend a few sleepless nights re-coding all your pages for Microsoft *Explorer*.

Joel Maloff: Let me sum up the opinion of the panel. Good luck.

M: Good afternoon. We're about a \$50 million company to the third quarter of this year, and I'm responsible for bringing up our Web site, which will be up about Thanksgiving. Question...

Bill Washburn: Could you clarify that, "bringing up the Web site?" Will that be the first thing you do with the Internet, or are you already doing other things?

M: That will be our primary application, although we will use electronic mail to facilitate better communications with our vendors and the like, and we'll be implementing FTP and some other services; but primarily to help people work with our company more easily and more effectively.

Question, though. Turn your attention now internally, to the company. Companies of my size and larger certainly have marketing and communications groups, and these people have long-term experience in the print medium and their whole paradigms are associated to print medium, advertising, direct mails, etc., etc. I see some real cultural conflicts arising, both structurally, in reporting structures and the like, and with power. And I'd like to have your thoughts on how to anticipate those within the company, and ensure that both the marketing and communications from the print media and the people who are focused on the on-line side of this can work together as effectively as possible.

Peter Henry Stair: Let me start this and then I'm sure Joel has some comments, as do the others. It sounds, if I can interpret from your question, as though it's a technology group within the company that's doing the Web part, and it's a classical press relations, public relations, advertising media group that's doing the normal print media. It sounds from your question as if they're two separate groups. Is that a fair interpretation?

M: Yes. I was chartered to do this because I have the background.

Peter Henry Stair: Okay.

M: [inaudible]

Peter Henry Stair: And without knowing your company [inaudible], because I can't get too deeply into this — but one of the things that we're continually counseling clients is that this is a new tool, but it's another tool. And it has to be integrated into the current campaign. It has to be integrated into the current press relations. It has to be integrated into the current advertising. It has to be on the fax forms and so on and so forth.

One of the most tragic things that can happen to a new Web site is to have someone from the outside call a company your size and say, "I'd like to talk to somebody about your Web site," and have the person answering the phone say: "What's a Web site?"

So internally as well as externally this has to become a new tool, but it has to become part of the culture. You have to integrate. And I suspect if they're higher in the power structure than you are it's going to be up to you to make sure that you integrate yourself with them, but integration is key. You must be part of the company infrastructure, and particularly the rest of the media and the campaigns. Joel?

Joel Maloff: Yeah, let me dovetail onto that. One of the roles that I tend to play... It's interesting, I had a lady come up to me in the booth yesterday. I was doing a book signing. And I explained that I act in the role as bridge between technical organizations and functional organizations within the company. She goes: "Oh, you play the role of hairnet, keeping everybody under control?" I said, "That's one thing I've never been called before."

Peter Henry Stair: From now on, it's "Hairnet Joel."

Joel Maloff: I always thought you had to have some to have a net. God, what a terrible time with what we're talking about.

The issue, as I see it, is that you need to talk not about our Web site, not about the Internet, but functional issues. And the organizations need to understand — where's the bang? Where's the value? If you're talking about traditional PR and communications companies, one of the first examples that I can cite to you that might be valuable is a distribution of press releases electronically. If they distribute their press releases today on paper, the likelihood is that they go out to various media, they sit in a pile, and they may or may not be seen. If you send them electronically, normally they are looked at. If the media people like what [they're] seeing, well, what happens is that they have the ability to simply copy from the electronically encoded media and cut it in. I send out two hundred press releases, I get coverage, and they actually spell my name right. And it's important.

That's just one example. Most of the reporters and editors that I've spoken to would prefer to have it sent to them in that way. It shortens their time. It also is much less costly than

trying to duplicate two hundred or a thousand press releases and send them out. And so my suggestion in your environment is talk about the business issues and the implications. What is the value?

One other example. If your internal corporate communications group is working with a PR agency... I've been a Vice President of Marketing. I have had ad campaigns where they've had to nail me down when I was traveling to look at copy, to review blueines. You can send me those files over the Net and I can look at them in a fraction of the time, whether I'm in Brazil, the Philippines or otherwise. It works. What I would suggest you do is talk about it as business tools, business issues, rather than a threatening technology.

David Sachs: It also seems to me... I was thinking about it as you were talking. It's a large enough company that somebody, somewhere clearly felt a need to have this happen.

M: [inaudible]

David Sachs: So one would like to believe that having asked you to do that — which clearly costs somebody time, energy, money — I found myself thinking: "So where is this?" Now that you've got it, the question is: "Okay. So what are you going to do with it?" And I do think it's a question of what's going on, what does that common boss have in terms of... I mean, maybe you all need to go do Outward Bound for a week or something and get to know each other, but there's clearly an opportunity there just to focus on the business side of things. It would be an interesting question to say: "We've got a brand new resource, how can we use it best to serve the purposes of this company?" Which, I assume, was one of the goals early on.

Tristan Louis: Now, one of the other things is [that you should] designate a driver on your staff, have somebody to talk to the marketing department, and also go to the marketing department and tell them, "Okay, please assign somebody we could have one of our team players talk to." And that will facilitate communications where you have one designated person in each of the group, essentially keeping all of the group up-to-date on what's going on.

Joel Maloff: I don't think you can tell the marketing department. I think you have to work with them.

M: Well, in my case I [inaudible]...

David Sachs: Bill, you said there was another question.

Bill Washburn: Sure, a couple more questions.

David Sachs: Many more questions.

W: Okay. Thank you. I was just wondering; we talk about how all of this is in the you know, early stages, the adolescent stages. We still don't know all of that. How long do you think it's going to take or what will it take for us to decide that this has now been mainstreamed enough that consumers accept it, and advertisers, even small advertisers — not the \$50 million companies, but the mom-and-pop tobacco store — has decided it's worthwhile to be listed on the Web or to have a Home Page on the Web, or to be a part of it? So what would it take? How would I measure that I have gotten to mainstream, and sort of what will it look like?

Tristan Louis: To a large extent I think we're getting there. Why are some of the major companies getting on the Net? Because their competitor got on the Net. And I think it's not going to be so much the audience getting onto the Net that is going to be important, but companies now just have the impression that they need to be there. A URL is now becoming as essential as a fax number, and I think we are finally reaching critical mass.

Joel Maloff: It's interesting that you mentioned mom-and-pop tobacco companies, because I happen to have a client that is a tobacco company, and in preparing a full-day training session for them I did a search on tobacco, and there is Joe's Tobacco and Cigar Store on the Net right now.

I agree with Tristan. I think we are reaching that already. I was actually taking a train from New Jersey into New York, and at one of the subway stations we stopped, and I looked out the window and I saw on an ad — a billboard — www.perfume.com. And when I start seeing URLs in New York City subway stations, I think we're reaching the level that you're talking about. We're about there. I think within another year it's going to be very well-penetrated within all levels of business and all over the world, not just in this country.

W: [inaudible]

Joel Maloff: They don't have to.

W: They're not going to have to. They'll...

Joel Maloff: You don't need anything more than a dial-up account today, and you don't even need that to be on the Web. And again, I think it's coming. It will be here. And I think well-penetrated, whatever that means, within a year.

David Sachs: We're working right now in Westchester County with the Westchester County Association. They've got about 800 member organizations, and they were asking exactly the same question. They said: "What do we do to help large and small businesses get there?" And as soon as you start to ask that...

When people wanted telephones in their offices, they didn't all go out and learn how to install telephones. They probably called the phone company and said, "This is what we need, because we have a business to run." And so what you're finding is more and more of a proliferation of these Internet presence providers. It may be that what your small business needs is a fax machine that's up and running, so that when the orders come in or when the requests come in somebody can fax them to them, period. They can still be "on the Web." They can still have a presence. They can still use it in their advertising. It just may be that they don't need to have all the technology under that one roof.

W: But isn't it...

David Sachs: But isn't that what?

W: I was going to say that isn't there going to have to be a consumer penetration deep enough that as an advertiser, I'm going to think...

David Sachs: Well...

W: You know, [inaudible].

Peter Henry Stair: Let me try this one.

W: It doesn't make sense.

Peter Henry Stair: Let me go back to your question, because I want to have some controversy here. This is the first time that I'm going to violently disagree with the rest of this panel. And I'm going to establish what is for me a criteria of criterion, whatever. Thank you.

Joel Maloff: That sounds like an illness.

Peter Henry Stair: I'm going to establish for myself a judgment into when I think it's reached critical mass. It's reached critical mass when if they took it away it would really cripple the way we do business, and it would really cripple everything else.

If we took the Web away today — we've heard a lot of people in this room, we've heard a lot of people in this conference [talk about that], but the American public and the world public in general probably wouldn't even notice. When we reach that — and we may be a year away, we may be three years away; we're probably not five years away, but we're in somewhere in that range — when that happens, if we were to lose it and that was critical, then it would be generally widely available.

M: Okay. My comment, having said that, I want to know how many of you agree with Pete.

And my last comment is if we took it away today the American public would be just fine.

Peter Henry Stair: How about a year from now? Twelve months?

M: [inaudible]

Tristan Louis: That [inaudible] this panel.

M: Not through today, people wouldn't notice it would make a difference in the American public. In other words, I disagree with Pete.

Peter Henry Stair: Why are we limiting it to the American public?

M: [inaudible]

Peter Henry Stair: Oh, no reason. But now let's try the same question with a telephone. If we took the telephone away today, would it be very bothersome to us?

David Sachs: I'd be very happy.

Peter Henry Stair: I'd be happy too, but would it bother us.

M: Joel's point, how many in the world...

Joel Maloff: See, I think that this is going to ultimately prove to be much, much more valuable to developing countries and in international commerce than it has been here in the United States.

We can take a train from Philadelphia to New York; it's no problem. But if you're out in Iceland, or if you're in Hong Kong and you want to do business elsewhere — Australia, the Philippines or otherwise — the key here is that this is a way for people to live where they want to, have the style of life, custom of life that they wish, and do business.

In my book I interviewed a fellow in St. John's, Newfoundland, who's a consultant. There are a total of 600,000 people in the whole province. There's no business for him there. But he can live there and do work because of the Net. And today, if the Net went away, I'd be out of business, and it's not because I'm an Internet consultant. The way I do business would be gone.

M: That's what I [inaudible].

Joel Maloff: And home-based businesses that are growing exponentially are being fostered. Whether it's the America Onlines, CompuServes, the Internet, if you took all of that away today, including those on-line services, people would notice.

David Sachs: I would give you just a couple of different perceptions. One is that if you look, for example, at *Business Week*, it now includes a page every week with the URLs of all the companies that are advertising there, and so you've got a page that wasn't there six months or a year ago. You look at the *Wall Street Journal*, and once a month they've now got their last-Thursday-in-the-month issue that has several large pages filled with lots of little boxes with URLs and all the rest of it.

And then there's a story that really supports what Joel was saying. We were in Australia this summer. Well, about two days before I had gone, I had read about a new piece of software that I thought was really neat, and so I quickly downloaded it and had it on my machine. It's a piece of software called *Hot Dog* that let's you do a lot of HTML quickly. I got to Australia, went upstairs to look in the room up there, and lo and behold, there are the two fellows who happen to be Australian who have created software, the software called *Hot Dog*.

Joel Maloff: And you didn't know where they were before?

David Sachs: And I had no idea where they were before I got the software. Probably, had I paid attention to the screen, I might have [known].

Tristan Louis: That's because you didn't pay the fees.

David Sachs: Well, no. It's because, it's, with — to the contrary, there were no fees to be paid until I tried it for thirty days. This part of this is the kicker for me; Pete and I went to talk to them. We said: "Oh, this is so interesting. You all are here in Australia, and how are you doing business-wise, and gee, you know, it must be complicated software, blah, blah, blah." The young man looks at us. "Wait a minute," he says. We say, "Well, how are you doing on your business?" He says, "Oh, it's neat." He says, "We found an Internet service provider in Atlanta, Georgia. It costs me thirty bucks to register with them, and for thirty dollars a month they're my site, shipping my software all over the planet."

So this guy is in the middle of nowhere in Australia and he's running a business out of Atlanta, Georgia. I never knew where I went to go get the software in the first place, and it's costing him a grand total of thirty dollars a month to be in business, and in his case he would be out of business if that service provider weren't there. He said, "Gee, if I did it in Australia, it was like a million dollars an hour, and they were going to charge me by the byte to ship the software." And we both looked at each other and we thought, "That's really an interesting

different kind of solution to some of this stuff.”

Joel Maloff: Two real quick comments. First of all, to Tristan’s comment, I didn’t know Generation X-ers cared about money. And secondly, before you get a shot back at me, there is an absolutely wonderful cartoon that’s been around for quite a while (I mentioned it in my talk the other day) with two dogs. One is sitting in front of a computer, one is on the floor and the question — and the comment is on the Internet — is that no one knows you’re a dog. They also don’t know where you’re located, how big or how small you are. And that is the wonderful beauty about this technology and community that we’ve created. And I don’t think it’s going away. I think if you unplugged it today in all of its manifestations it would be noticed, and to the detriment of emerging countries, emerging businesses and big businesses as well.

Peter Henry Stair: Joel, I agree with you, but let me point out that this is not yet critical mass.

Joel Maloff: Bill, you’ve lost control.

Peter Henry Stair: It will be critical mass when all of our mothers have Home Pages.

Tristan Louis: Well, I’m going to address Joel’s comment about money...

Joel Maloff: Bill’s trying to say something.

Tristan Louis: Two minutes. tops. Well, when we found out that there was a lot of money to be made on the Internet, I think we started to take notice, and when we found out that you guys were getting paid the big bucks we started asking for them.

Joel Maloff: Bill, did you have something?

Bill Washburn: Yes, I wanted to ask you — having made your little poll a minute ago where we all decided how complex it was [inaudible] American public or the world public today, how many months, years is it going to take before it will make a difference? One year? Two years? Three or more?

Tristan Louis: Never?

Bill Washburn: Never? Nobody.

David Sachs: I would offer an observation. In support of the sooner rather than later scenario, I was in the Middle East in January in four rather exotic countries: Bahrain, Dubai, Abu Dhabi and Qatar. The title of the talk was “The Information Superhighway in the Internet.” They did nothing more profound than put a tiny little picture of me in the paper and a paragraph, and they had no clue in life who I was. Every single city, it was standing room only. Every single city they turned people away from these presentations, and these were four parts of the world where, at least in January, there was no Internet activity to be had. But they were hungry to know more about it, they were eager to figure out ways to use it. They were actively thinking about business opportunities once it existed.

And as of the first of August, when I went back there in late July, there is now Internet activity in that part of the Middle East. So I would submit that sooner than we think there is clearly going to be a proliferation of these services, and then I think you’re going to see Pete’s

scenario that says: "Take it away and you're going to cause a lot of harm in the process. Take it away and you're going to quickly put a lot of people out of business."

Tristan Louis: I just want to address the fact that there's also a lot of danger in getting too acquainted with the Internet. For example, there are a lot of people for whom I only know their e-mail address. My e-mail station goes down and I'm essentially helpless. I'm at that point where I don't know their phone numbers, I don't know where they're located in the world, I only know how to e-mail them. The problem with that is that if we come to a total network breakdown — as happened in 1988 with the [Jim Morris] worm — it's going to take days to bring it back up. And if the Internet is to become mainstream we're going to have to make sure that there is more communication using the telephone and the fax machines than using the Internet.

M: I just wanted to tie together three threads that I heard you guys talking about before, and then sort of ask for comments. One is that I came out of the hacker [environment], Tristan, and I'm probably about your age. However, when we start talking about commercial acceptance, I wouldn't want someone up at 4:00 in the morning writing the code that generates my P&Ls. And that ties into another theme Joel was talking about, about how you want to own the transaction, and that a lot of certain commerce solutions and other people want to own the transaction. If you're in the retailing business, or a lot of other businesses, you know that if you want to really make money you have to own your transaction. And to tie that in with the other tool theme that you were saying, it's just another tool to use.

There's a lot of other tools, technological tools available to organizations, like automated accounting systems for finance, and EDI to manage inventory with suppliers. I was wondering if either [of you] had the best practical examples of organizations that are tying the Web in as a tool for large applications, or vendors that are trying to solve those sorts of problems. The Web can spit out these ASCII tables, but how do I get those in and out of my accounting system and to my suppliers and things like that?

Joel Maloff: Let me start out with that. A couple things. When I start with a client, the first thing I tell them is forget about the Web. Forget about the Internet. Let's talk about what you want to accomplish. What do you need to do? And then let's look at all of the alternatives, whether it's Internet or EDI using point-to-point leased lines, or dial-up services or framed relay. Let's see what you want to accomplish. Then, when we determine what they're trying to accomplish, as in the case with EDI — EDI can be handled over the Internet as a transport medium using [Primrose] or Sterling Software capabilities or any of the others. Again, it's... I mean, I don't want to repeat myself. It's a tool. Which one works? Which one doesn't?

M: I'm looking not so much for that, but sort of the more concrete level.

Joel Maloff: Right.

M: Do you have examples of best practices and someone that's taken the Web and turned it into [inaudible] and done really well?

Joel Maloff: Yeah.

David Sachs: Yeah.

Tristan Louis: Yeah.

Peter Henry Stair: The three of them said, "Yeah." I was going to say, "No." In terms of total integration into a business process where the Web is just one more mechanic, I would have to struggle with that, other than the distribution of information. But in terms of a total corporate set of transactions I'll pass it down the line because I'm not aware of one.

Tristan Louis: I think Netscape probably did a pretty good job at it. One of the things is that we're seeing the Web also become a tool for groupware, and Netscape is going into that general direction. Lotus is trying to protect its market share on Notes, and several other companies are currently looking at the Web as also an internal thing. We're seeing more and more internal Web sites pop up in companies; Digital already has a product out. Netscape has bought out Collabra, about a month ago, I think — although in Internet days, it seems forever. And we are going to see a tighter integration of the outside Web, which is the one that will be viewable by everyone on the Internet, and the internal Web which will be available only to employees within the company. That hasn't happened much yet. But with a number of Lotus Notes users out there, I think we're going to see that pop up within the next year or two.

David Sachs: I would just say that I'm not aware of a company where every single aspect of the what they're doing is probably being handled well today, but certainly there are ones we can start to look at, really interesting and probably important things happening that are both either making somebody money or saving them an awful lot of expense. Federal Express is a perfectly good example. Their one page that lets you track instantly and effectively where your package is at any moment in time, from the moment it leaves your hands or somebody else's until it gets to its destination; that is both awesome in its simplicity and powerful in terms of its effectiveness. I read some number that said they were getting 90,000 requests a month.

Now you have to translate. If it did nothing but save 50¢ on every single one of those transactions, there's real money that's on the table. You look at something like GE Plastics, and we were showing this to a... Pete and I have been teaching a seminar here called, cleverly enough, "Seven." What is it? "Seven Habits of Successful Web Sites."

If you look at GE Plastics, they've clearly got a very tight market. I'm not personally interested in all of their extrusion processes and whatever else they're doing, but they've got fifteen or twenty thousand pages of documents that are available in a Web format. That was not true two or three, or whatever number of years ago. And suddenly: (A) it's not being distributed, (B) it's timely, (C) it's effective, (D) it works, (E) go fill in the blanks. But in other words, you can start to look at examples, and I think what you're seeing is the company's saying: "Where do I start the conversation and what do I do to effectively increase this aspect of my business?" And probably that makes the most sense, anyway, before you start to say: "Is it a universal application for everything in sight?"

Bill, what do you want?

Bill Washburn: I wanted to just be ready for the next question.

Tristan Louis: Okay. I'll just address the fact that you mentioned GE Plastics, which is an interesting example. I can't remember the name of the company — I sure remember their URL — but there is another plastic company out there which is much smaller than GE, and they've set up a site called www.polymers.com, which is information for people in the plastics industry. And they have managed to really create an international image out of that site.

Bill Washburn: Any others? Yes.

M: Thank you. Gentlemen, I'd appreciate your comments on theory that some people were discussing recently with me regarding Web sites that are commercial endeavors, where they are making money. Not Web sites that are advertising or your mom's Home Page with her recipes, or any of the myriad like that, but the really significant content-oriented, revenue-generating sites.

It's apparent that because of the confusion on the Web it's difficult for users to find what they're looking for; one concept is that they will develop these tremendously vertical applications, where you go one place for this and everything you want is going to be there — cars and insurance and accounting, and you know, whatever — and the analogy was that it was like unto the other industries that have evolved, where once large corporations got involved and had the resources to continue to raise the benchmark, basically either buy up, adopt or shove out the cottage industry people that were beginning to develop these things. And I'd be interested in your opinions on that.

Do you think that's what's going to happen with the Web? Do you think that one, two years down the road that it's going to be essentially just big corporate control of those content sites that are actually revenue generation?

Peter Henry Stair: No, I think what we're seeing is exactly the opposite.

David Sachs: Why don't we take a vote on the panel? How many of us think yes?

Peter Henry Stair: It's the small business. It's the entrepreneur, the start-up, the very small industry that's challenging the top-heavy older industries out there. One of the examples we often use is Matshusta. Matshushta's Home Page, if you go look at it, is quite handsome. Matshusta in, I believe the *August Fortune*, was rated the largest corporation in the world. We also show them Big Wind Kites, which is a one-man kite shop in Hawaii. Big Wind Kites looks better. Now, they're not going to take Matshusta's business away from them...

M: [inaudible]

Peter Henry Stair: Well, who's Matshusta?

David Sachs: What did you mean? Are you asking how successful those sites are going to be?

M: Yeah, I'm talking about sites that are generating revenue.

Peter Henry Stair: Sure. Yeah, and what we're seeing now, I think, is that the smaller sites are actually generating revenue for the smaller entrepreneurs more quickly.

M: Right.

Peter Henry Stair: More quickly than the corporate sites, which are tending to be extensions of their public relations department.

Joel Maloff: Yes. Let me address it from two standpoints, first of all from my own personal standpoint. As I mentioned earlier, I actually sell reports. The reports are doing exceptionally well. I am a one-person company. And so, yes, I think that they will generate revenue. I'm not

going to generate the same amount of money Matshusta might generate. I'm not selling tractors. The other thing, too...

Tristan Louis: You don't do tractors?

Joel Maloff: No, I don't do tractors. The other thing that's important, is that if you look at the very large companies — I don't care how good and how agile they are — they can't move as fast as I can. I am the decision-maker. I am the cook and the bottle washer and everything else, and so I have the ability to be flexible. What this medium does is give me the ability to compete, and compete in an economical way. I have the ability to advertise in an interactive fashion and let people know that my services are available and they can avail themselves as they wish. I think that it is an empowering technology rather than a limiting one. Sure, the big guys are going to be out there, and they're going to do lots of good. But the smaller ones, you know, the little gnats, are always going to be much more agile and much more effective.

David Sachs: And if you think about it, what you've really got is something that has lowered the barriers to entry and lowered the... In other words, if you're going to compete in a global economy, if you were going to do that ten years ago you probably needed to think about the cost of getting your items around the world, the cost of that. How does one effectively live in the wilds of Michigan, for example — I just made that up — and let somebody know in the Philippines that their services might be both useful and accessible?

You can't hire an advertising company halfway around the world to work on your behalf on the offshoot that maybe you'll get some business out of it. But suddenly you've got a barrier to entry that's remarkably low.

And so, in an interesting way, I really think it's moving in exactly the opposite direction. I think you're going to have big companies, or maybe conglomerates... You had an announcement, whatever it was, this week, late last week, about all these insurance companies. You're going to be able to, in effect, do one-stop shopping to go do that. That's wonderful, but that's probably going to not change the dynamics of other people who want to do what they're doing. It just says that's another opportunity and maybe it's going to be in a different way. But I really think the barrier to entry has gotten lower and lower. The cost of the hardware, the cost of the software is getting dramatically lower day by day. That suddenly changes the whole dynamics of this and, if anything, gives all of us more opportunities than we ever had before.

Tristan Louis: One of the interesting things that is happening is essentially the switch from the publisher controlling everything, and the producer, the big Time Warner and CNN controlling everything, to essentially those folks being marketers. You're going to go to them with your product and they are going to market your product. On the other hand, you can also go at it your own way and market your product. You might not be quite as successful. Hopefully, we will be able to do that.

Bill Washburn: It seems to me there's a variation on this question I'd like to at least put before the panel very briefly, and that is that potentially there could be a symbiosis developing whereby the very successful content providers — who are small and generating revenues become the immediate targets of purchase for larger corporations — that they themselves are perhaps incapable or not interested in doing things as well. At that point, if that becomes a symbiosis, where does that leave the rest of the Internet community in terms of what the benefits are to them, or is it just simply not an issue?

Tristan Louis: To a very large extent it's already happening when you've got America Online buying *Global Network Navigator* from O'Reilly for what was it, \$10 million I think, and then repackaging it as a service. And then you've got Dennison turning around and buying *Lycos* for an undisclosed amount. We are at that point where big companies are trying to buy an edge into the market, and that is going to at some point drive the price of Web sites up if you are an independent creator.

Actually, last week as I was surfing (one of the few things that I was able to do last week), I stumbled on the first page that said: "Corporations please take notice. This site is up for sale." We're going to see more and more of that come around. You can walk around this floor, and if you've managed to make a name for yourself on the Web, you have VPs crawling all over you, asking you how much money do they need to throw at you, how much money they need to throw at you for you to go your own way and set up your Web site.

Bill Washburn: Last question.

M: A year ago or two years ago, you gentlemen were probably saying that the opportunity was for Internet service providers, that that was going to be an entrepreneurial opportunity. That window is probably closing because there are a lot of them out there. The next logical phase for entrepreneurship might be to provide third-party services to support those Internet service providers. I'd be interested in your views on that and what you think those opportunities are.

Peter Henry Stair: The "hot set." I'll start here. The "hot set" at the moment appears — not only from the interest of this audience, but the interest here on the floor — of what we would call Internet "Presence Providers." Joel mentioned outsourcing a few moments ago. There are a lot of people who want to be on the Web but really don't want to do it themselves, and so the hot opportunity at the moment seems to be able to do the design, do the support, do the presence, if you will, on this WorldWide Web. That seems to be one hot opportunity.

Another is the software entrepreneur. There's so many new pieces of software out there; some will survive, some will die. But the ones who survive have tremendously powerful opportunities. And without complaining about Generation X and their money, most of them are very young. Most of the software developers in that field are very, very young. So those are two, I think, very hot opportunities at the moment. I agree with you that the service provider field has become pretty much a commodity.

Joel Maloff: I have two comments. First of all, I agree partly with Pete's last comment that the Internet access provider marketplace window is fairly well-closed now, except for geographic niches or vertical industry niches in the United States. It is absolutely not closed elsewhere in the world, except for perhaps a few places in Asia like Japan, perhaps Canada, maybe England. Everywhere else it's wide open. And then in terms where I believe the hot areas are, if you listen to most of us talk you'll hear us still talking about technology.

I think the time has passed for technology. Let's talk about applications. I want to see businesses that are incorporating Internet as part of a value-added service — language interpretation and translation services where I can send a proposal. Let's say I'm doing work in Dubai; Pete and David mentioned Dubai. I don't speak or write Arabic. I send them my proposal in *Microsoft Word*, across the Net, and they interpret it so that it is correct and accurate in that language. I can submit it in that language. That's a good one.

There are other ones — companies that do domestic surveillance, and maybe we don't like those. But let's think about the specific business applications and that's where the bang is going to be in the next wave. What do I do with it now, beyond how do I do IP? How do I do

Web hosting? Those are all good. But let's look at the next wave.

Tristan Louis: I'm going to break from the panel by saying that I think the Internet access communities still have a lot to offer. What they need to realize, however, is that their job is not just one of connectivity but one of creating a community within their own connection area.

For example, in my ample time I am running an ISP in the New York area and one of the things that we've started is we... While we were adding phone lines, we decided to have some people come in and also help us out. And from there, those people started talking about Internet issues, globe Web sites, etc. We turned it into a gathering, a weekly gathering, and as a result users are re-signing with us year-in, year-out, and more people are coming in year-in, year-out, because of that community, because they know that when they connect to our site they're not just going to get Internet connectivity they're also going to meet new people and be able to share that Internet experience with them.

David Sachs: I would just add one other comment, and part of it is clearly a function of what I do for a living. I think the opportunity for education is enormous. I mean, even if the numbers reported in this week's survey are accurate, which says somewhere in the U.S. and Canada you've got 24 million people using this resource, that implies a huge number that is nowhere close to using this resource. I was at a dinner luncheon last week in New York with lots of successful executives from lots of different businesses, and I was sitting at a table with somebody who was going on and on and on about — I mean, he had invited me to the luncheon — he was talking about the Internet like this was the best thing since sliced bread. Finally, one of these guys interrupted me. He said, "You know, with all due respect," he said, "I don't even know what you're talking about." He said, "I know what the word is. I see it in the paper." He said, "I couldn't tell you what it is, what it does, why I would care about it, how it's going to help my business?"

And so, in an interesting way, I think we've got an enormous amount that is happening, but I think the potential is still — it's not like all the gold has been discovered in California or wherever. It's that you've got a fair number of people who are aware of this, but I think the opportunity... I mean, I look at the books that are out there today. You've got books all over the place, and you know, why is Joel writing a book, why are we writing books? Part of it is because it's not intuitively obvious. People are still trying to learn this thing is. How do I integrate it into my life? How do I get the tools that are, remarkably, getting better and better? I still have that learning curve that says: "Well, how does that become an easy process for me to do?"

So I would add a different perspective that says, forgetting about Internet and service and access and all the rest of it, I think you've got a huge number of people out there who need to know a lot more, and want to learn a lot more, who need help and support in the process of doing that. You've still got sites that dabble in technical gibberish, like IP addresses and dynamic and blah, blah. I mean, you get into a whole world that many people never wanted to be in in the first place. So I think there's another whole sort of interface in there, that human side of things that teaches people how to use things on their own terms.

Bill Washburn: Ladies and gentlemen, thank you very much for your questions and your comments, and I hope you have enjoyed the conference.

INTERNET VILLAGE WEBABLE! THE WEB'S 'FIRST-STOP-SHOP' FOR PEOPLE WITH DISABILITIES

MODERATOR

Laverna Saunders

Dean of the Library and Instructional & Learning Support, Salem State College

SPEAKER

Michael Paciello

Program Manager, Vision-Impaired Info Services, Digital Equipment Corporation

Laverna Saunders: I'd like to welcome you this morning to Internet World. This Track is [the] Internet Village, and you are in the Waterfront Ballroom. If this isn't where you want to be, this is a good time to move on to the session where you think you should be, whatever that means.

Our first presentation this morning will be by Michael Paciello. The WorldWide Web has been painted as an information superhighway that will lead us all to the promised land; and for many people it will, but not necessarily for the people with disabilities. The Web can truly be a tangled mess woven by entrepreneurs who have no idea that millions are being left in the air. Does anyone really care? What are the so-called barriers that the blind, deaf and physically-challenged must break down in order to access the Web? Are there really any solutions at all?

Michael Paciello, Senior Usability Engineer and Program Manager for Digital Equipment Corporation, Vision-Impaired Information Services Program Office, has been a consultant in the field of assisted technology for people with disabilities since 1984. He was recently elected as chair to the Electronic Industries Association, Assistive Devices Division, and is on the Board of Directors. He is co-founder of the International Committee for Accessible Document Design, the organization responsible for the accessibility codes developed and included in both HTML and SGML standards.

If you want to hear more from Mike, you can come back to Boston in December, when Mike will be chairing an international one-day workshop at the WorldWide Web Conference here and will focus on the subject of accessibility of the WorldWide Web.

His presentation today is entitled "WebABLE! The Web's 'First-Stop-Shop' for People with Disabilities." If you want to communicate with Mike after the meeting his e-mail address is mpaciello@webable.com and his URL is <http://www.webable.com>. Without further ado, I'll turn the presentation over to Mike.

Michael Paciello: Good morning. I'd like to thank you all for coming here to hear me speak this morning. I hope that those of you that are here understand and realize the importance of an endeavor that myself and many of my colleagues are trying to work on, and that is the accessibility of the national information infrastructure, which obviously includes the WorldWide Web.

Just a couple of quick notes up front. Are there any people here, any with us, who have a disability? Any that are deaf or blind that are with us? Okay. Are you deaf? Okay, how are you?

I always think it's very important before I start any presentation to determine who my audience is, and the first people I am concerned with are those who have a disability. Quite obviously, that's the business that I'm in. I am also concerned about those who may be working with or perhaps employ individuals with disabilities, so if you are one of those, raise your hand. Excellent. Very good. How many employ individuals who are blind? None. Okay.

If you are interested, before I get started, one of the companies that I've been working with is a company by the name of Berkeley Systems. You probably know them better for the

screen-saver software that they make; however, Berkeley Systems is also very well known for putting together a piece of software which is called a "screen access" or "screen reader" for individuals who are blind or have low vision, and it is compatible with the *Netscape* browser. The blind can actually use a graphical user interface browser with a Braille output display or with a voice synthesis. If you'd be interested in getting a demo of that, I have just five disks — four diskettes — that they sent me of the demos. You can see me after this particular session.

As I mentioned, I've been involved in the disabilities world for about 11 or 12 years now. I am a consultant in the field. I serve on several different committees, a couple of which we'll actually show here — we hope, with the server being somewhat problematic — a little later on. I serve on the Mosaic Access Project, which is a committee of individuals who are working out of NCSA to work on accessibility of browsers — not just the *Mosaic* browser, but browsers in general.

I also am a consulting partner to the Universal Access Project, which is part of Vice President Al Gore's NNI Initiative. We are working on developing standards and guidelines for the national information infrastructure and the global information infrastructure and, as I found out a couple of weeks ago, folks in Europe and their EII consortium have now asked us to be involved there, so we're working with them.

I'm also involved now with the folks from the W3 Consortium. They've graciously allowed us to put in, at the very last minute, a special one-day workshop at the WorldWide Web Conference that will be coming up in early December. If you'd like to find out a little bit more about that, or if you'd like to come, please see me after this particular session.

This particular session, as you well know, is entitled WebABLE. I want to say up front that it's not meant to be something where I'm tooting my own horn, because this happens to be a site that I've put together and have developed. Rather, it is to serve exactly as what I wanted it to do when I developed it; it's to be an information repository, a place for individuals who either have a disability, employ people with disabilities, or somehow have an interaction with individuals with disabilities, so that they would always have a source place to go, a first-stop-shop as it were to find out any information that they might need in relation to people with disabilities.

There is a plethora of titles and topics and issues related to that, and this site is not just focused on things related to situations going on here in the United States — the Americans With Disabilities Act, for example, or Section 508 — but rather it is also positioned as an international site, so we have sites here from all over the world, papers, conference sponsors, product and solution manufacturers who are located literally from one end of the earth to the other. That was my goal when I set this up about six months ago.

I'm very happy and very glad for the support that Meckler has given me in relation to being able to show and display these things. As you may know, in the October issue of *Internet World*, they actually did an article on disability sites, so you might take note of that if you haven't picked it up. I'm not sure if they're actually handing it out here, or if they're selling it, but the November issue — I'm sorry — of *Internet World*, on page 141, lists briefly a few sites that are actually located and positioned for people with disabilities. That is just one more way of their showing how they support this work, and we really appreciate that.

When I designed WebABLE I designed it as a usability engineer would — which is my other work, my part-time work, even though it's supposed to be my full-time job — so that access for everyone would be the key. That's what we've been striving for. We're looking for access for people who are blind, so we're looking up projects and focusing on things here that include, for example, voice synthesis for individuals who are blind. We'd like to make sure that individuals who use refreshable Braille displays — does anyone know what a refreshable Braille display is? One person, and I think we probably have about 30 or so here.

Refreshable Braille display; let's see, how many saw the movie *Sneakers*? All right. A few more. If you remember in the movie the individual who was blind, as he was interacting with the PC, was using a device that kind of looks like a keyboard but, in fact, on the front panel are the little dots that come up very, very quickly. That's a refreshable Braille display, and essentially what that does is it reads the ASCII streams as they're coming in and just pops them up and translates them into two lines of Braille; usually they're 80 columns and 80 character displays, two columns all the way down. So that's a refreshable Braille display, and this is an item that is very commonly used amongst the blind as they try to hop from site to site.

So it kind of gives you an idea of the challenge that they have. A graphical user interface, for example, is not intuitive in the sense of sending back ASCII streams. It's supposed to be sending pixels, it's displaying pictures, so how does one go about getting the ASCII? Well, that's one of the things that we've been working on, and WebABLE provides hits and hyperlinks to showing that.

We've also been working on one of the places we'll visit in a little while, the Trace Research Center. They're located up in Madison, Wisconsin, and the director is [Greg Vanderheiden]. Greg was here just last week. He and the folks at WGBH in Boston put on a small, half-day forum in which he gave a display of a tactile information kiosk that was also accessible to the blind, to the deaf and to those who are physically challenged in one way or another. That kiosk was totally accessible.

There wasn't an individual who could not use it. For individuals who are deaf, there were captioning cues where there were perhaps calls that would normally be generating other sound or audio cues, so every time a display came up that might have shown a movie or a video clip it also had an attached caption clip with it.

For the blind, the whole kiosk is completely tactile. There is a square, so there's a defined region for an individual to feel and run his hand along the screen. And there's voice synthesis and read-back of everything that's actually on their display, so that a blind person can actually use all of the menus, go from icon to icon, menu to menu, list to list, all the way down the line and run that kiosk completely.

For those who are physically challenged — and this is another very interesting aspect of my work that helps us to move into some of the next-generation devices that we've been working with — there is infrared access on these particular kiosks. So if you have an individual, for example, who is paralyzed from the neck down, a quadriplegic who has no physical means of accessing the buttons, in many cases it is also true that they're not even able to speak so that they can be understood. By using small infrared devices that are attached somewhere to them — or perhaps in some cases that we're also looking at, on wheelchairs — they can control what goes on in the screen. So that's another thing that you can find located here on WebABLE. Again, I mention close-captioning for deaf users and descriptive video for individuals who are blind.

Again, if you're not familiar with descriptive video, this is a server that was actually invented and promoted by our folks right here in Boston, at WGBH. It has become almost an industry standard now in the sense that they have learned how to take a video, motion videos, and during the pauses where there is not any dialogue or any exterior sound effects, they clip in narration so that you describe the action that's going on to the blind user.

Now, mind you, all of this is available on the WorldWide Web. That's the key here — that these things that typically are associated with being inaccessible to people with disabilities are there, and are available for being keyed on. We're looking at building or promoting the use and the building of cognitively-enhanced or easy-to-understand interfaces for those who have cognitive impairments.

Let me just briefly give you one way that I've done that on my own site here. I've created a toolbar here on the WebABLE site; and you'll notice that the toolbar actually uses blocks. Now, I did that on purpose because blocks are, generally speaking, one of the first foundation stones that are used in teaching young people, so individuals who have cognitive impairments can immediately identify with blocks. Along with those blocks we try to make them so that they can be easily identified.

You'll notice that each of the blocks has an association directly beneath it, what it actually points to. Of course, that's a menu also for the blind who can't read those graphical images; although, in fact, each of those images has a text description behind it.

The idea is to try to create simple interfaces that are laid out in an order that makes it easy for individuals with disabilities to access. There are a lot of other provisions here on WebABLE, and we do invite you to visit there in your own time. For example, there is a list — and, again, we'll touch on this in just a moment — of assistive technology manufacturers who have their own WorldWide Web sites, and you can connect to all of them from WebABLE.

In the case of assistive technology manufacturers or solution providers who do not have their own Web sites, generally speaking, most of them — I have yet to run into any who currently do not have an electronic e-mail address through CompuServe or through America Online or some of the major service providers. Those are also listed there.

We're currently working on an image map — it's kind of tricky because of the fact that we have people with disabilities who are accessing this site on a daily basis — that will, at least right now in the United States, locate and provide the address index of every technology manufacturer, every federal, state and local agency that helps individuals with disabilities and provides funding and direction. They can click on the state, click on the city and get help right away by just accessing the site. There are about 30 or 40 research centers that are located on this site. Again, those are international research centers.

All of these research centers are focused on the needs of access for people with disabilities across the board. Not all [of them are] with the Web, but many of them are involved. Trace Research Center, for example, is. The University of Toronto is and they're working on the virtual reality modeling language, and they've just received a significant grant from the Canadian government to do that. And there are several other sites throughout the world, the folks in Europe and Asia.

Of course, we provide links to service centers, consultants in the field who have their own Web sites, and mailing addresses for non-profit organizations and their services, for example with recordings for the blind and dyslexic. They have their own Web site; I'm actually working on a site right now, right here, for the National Braille Press to get them up on the Web and then they'll be accessible.

So those are the type of things that you can find on WebABLE. I'll just turn to my notes here, and if you'd like we'll take just a couple of minutes and we'll shoot over to some of the sites to give you some idea of what things are available in WebABLE. The other thing that I'm going to do this morning is give you some pointers, if you are interested, in designing accessibility into your Web site. That's like an added thing that I've kind of thrown together.

As I mentioned, there are a lot of different things on WebABLE which you can use to your advantage. One of the things that I always remind folks is to sign in at the registry because I maintain a mailing list that is accessed by hundreds of solution providers and manufacturers, and it also helps me to send out updates on what we have provided here on WebABLE and Net sites and whatnot.

As you can see over here — and I'll focus on the Web sites — the first thing I do every month is I update the news section so you get an idea of the type of things that have been added. As I mentioned here, one of the things that we're working on right now is designing this

one-day workshop which will be available or which will take place on December 11 — that is actually the date of the conference down here in Boston for the WorldWide Web. [This section of the site] provides information related to registration for that particular conference.

You'll also note that this month we've just started up a library where we're loading several documents, guidelines, White Papers and things along that line for individuals who are concerned about people with disabilities. One of the papers that I left in the back — if you haven't had a chance, please feel free to take whatever you want from the back — is called *Access Taxed*. This is a directory service of Internet sites, FTP sites, Gopher sites, WorldWide Web sites, Telnet sites and all the way down the line, sites that deal or serve the needs of people with disabilities. This is also located up on WebABLE, and you can now just download that to your own site, or to your PC or to your desk there. Then each month I add in the new sites that have been [added]; sometimes, as in this case, they're research papers, and as you'll see they're the hot job of browser papers there.

For those of us involved in disabilities, we are very concerned about the *Java* language and the browser itself and its accessibility. Last week I had the opportunity to talk with the folks from Sun and they've guaranteed me that they will now focus on accessibility to make sure that the browser and the language itself is accessible for people with disabilities. So we're trying to get ourselves into as many areas as we possibly can. Generally, I always recommend that you try to go over to the "What's New" area and that will keep you up-to-date on what happens.

The next thing that we're just getting started with is the WebABLE library. As you can see, I can't even count because this is the article on the White Papers and it's supposed to be two and it only says one. I keep a running list of how many papers we have... We're just getting started with this.

One of the things I would like to point to that is of interest is the Adobe Accessibility Plan for PDF and Acrobat users. This is, again, one of those very important issues for us in the accessibility field, and actually getting involved with them was almost a war at first.

What happened was last year when NEST — which is the federal agency that develops the standards, the federal standards — decided that they were going to redefine electronic document interchange within the federal government, they were focused on the PDF output. PDF, in and of itself, is a graphical output and is totally inaccessible to the blind and low-visioned. In one of the consortiums that I belong to that was mentioned earlier, the International Committee for Accessible Document Design, we were able to contact the folks at NEST and let them know that it was inaccessible. They have, obviously, the largest population of employees with disabilities within the federal government, and they are individuals who — in fact, one of the directors of the IRS is blind, and based on this standard, would not have been able to see [any computer files with this program].

In fact, the way that they are doing it right now, he can't even use the IRS forms that have been put on-line, the ones that his own department developed. So we got involved and, of course, this brought in some issues with Adobe; and we're just really a small consortium of about ten people who work internationally on developing standards and information standards. The good thing about that is it turned out that Adobe was willing to work on accessibility and they've actually developed a plan that they are actively working on right now — and that we are working on with them — to build accessibility viewers for individuals who are blind and low-visioned.

So this was really something that was very exciting for us because, like I said at first, there was a lot of resistance; and when Adobe actually took the time to fly us out there at their expense and meet with them to talk with them about accessibility and what things needed to be done, they were very accommodating. And we believe that things will be worked out.

These are the kind of things, again, that you'll find in the library on WebABLE. Another thing that we'll obviously provide are news briefs, new product announcements, and some of the conferences. Now, these conferences tend to be conferences related to people with disabilities. I just returned from Minneapolis about a week and a half ago for the Closing the Gap Conference, which is a very popular conference. Conference announcements and registration things are listed there for people with disabilities.

Then, of course, I have what I call some of the special features. A little reaction there. This month we have focused on putting the "Access Text" directory listing there for individuals to download.

There is an article on how to make the Web accessible for the blind and visually impaired.

I always have a site of the month that's a disability site, and this month it's Project Do It. Project Do It is based out of the University of Washington, and they just received an award for their site; this is mentioned in the article in *Internet World*. Then, as you'll also see here, I have put together or solicited surveys of one nature or another.

This particular one was one that was sponsored by the Electronic Industry Association's Assisted Devices Division. What happened was that we conducted a couple of focus groups working on trying to develop guidelines and standards for consumer electronic product design. This turned out to be very, very successful. We put up a form, made it easy for folks to sign in and register, those folks who were going to the conference and attending, and then eventually this information was sent right back to the EIA. We had two very successful focus groups; the EIA will actually be putting this out in document form on the Internet once we've gathered everything, probably by the first of December. So, again, another one of the things that is very helpful.

One of the things that I mentioned that I would also do is provide you with some of the design guidelines. If you're working on a Web site and you are considerate of the needs of individuals with disabilities — now, there isn't a rhyme or reason per se that is listed here, so don't take these necessarily as the top ten Dave Letterman hints for designing your Web site for people with disabilities. That's not the point. These are just important ones, and these tend to be the ones that we find are most useful.

The first thing I tell everyone is to be sensory aware. When you're designing a site — oftentimes before I do anything I'll close my eyes, I will keep my arms to my side and I will mentally tune out any sounds so that as I'm designing each page I'm cognizant of the needs of individuals with disabilities. That's usually the very first thing we try to do.

This whole presentation is basically positioned as an awareness presentation, so be sensory aware. Try to find out, try to determine what the needs of individuals with disabilities are. I can tell you right now you will never be able to design a site that is fully and completely accessible to every person with a disability; it is literally impossible. However, you can reach a great percentage of those individuals, and when you accommodate them it makes it very easy.

I will also tell you that there is a very, very high rate of individuals with disabilities who are Internet-savvy. They live on the national information superhighway. These individuals very often can't find employment, not because they can't work, but because people won't employ them.

In some cases it is because they can't get to a place or physical location; oftentimes they run businesses out of their homes, and having electronic connections is extremely critical to their lives and to their business. So they're there and they're using it and they've been out on the Internet for years and years and years.

W: [inaudible]

Michael Paciello: [Is there] a number for individuals with disabilities who are using the Internet? No, there isn't. I can tell you that there have been some attempts to do surveys. The American Council for the Blind is doing a survey right now to try to determine how many of their blind members are connected to the WorldWide Web and the Internet. But even then, that's only a small focus of people because that's only individuals who belong to that consortium.

[Gallaudet] is also putting together a survey to determine how many deaf users are out there on the Internet. The figure right now for the United States is that there are about 50 million individuals with disabilities; by the year 2000 that number is expected to get close to 80 million, and that's because of the obvious rise in age in the population. That's just here in the United States. I can't even guess at the number of how many people with disabilities exist in the world, but the percentage is much higher outside of the United States than it is here.

So that kind of gives you an idea. People often talk about the market for individuals with disabilities and that's the reason why they don't do things. It's there, you just have to know the numbers.

The second hint is design the server, the browsers and the authoring tools. These are the three primary things you can probably throw in the operating systems. For example, I left back there — and I notice that they were the first things that were gobbled up and I expected that — the Microsoft Guidelines for Accessibility and what they've done, particularly what's available in Windows 95.

Are there a lot of PC users here? Raise hands. Lots of them. How many know that there is an accessibility option in the Windows 95 interface? Now, there were about 15 to 20 hands that went up when I said that, but only four of you raised your hands about the accessibility option.

That module is there. It's available through the control panel and in the next month I will be starting to give seminars on exactly how to use those accessibility options. I will tell you that this happens because it's happened within my own company, Digital Equipment, how system managers before they give you your PC turn [the accessibility option] off because it's a memory hog.

Well, that's not really true at all, and the more individuals who know about the accessibility option the better, because they actually provide some very practical utilities, for example with the ability to do large-screen magnification. You don't have to necessarily be totally low-visioned or blind in order to use screen magnification; I know individuals who just have poor sight or wear eyeglasses and prefer to have screen magnification. Those are the kind of tools that are available there.

If you didn't get one of those handouts and you would like one, make sure I get your card after this session and I'll leave plenty of time after the session so that we can talk.

So we have operating systems, we have the folks who are working on the servers, the folks who are developing the browsers, and the authoring tools.

An excellent example of an authoring tool corporation who has worked extremely hard in accessibility is [Softplate] out of Toronto. They have built *Hot Metal*, which is an authoring tool for the Web, that's totally accessible to individuals with disabilities, particularly those who are blind and low-visioned.

We try to encourage that, and we're trying to partner with as many individuals — when I say "we" I'm usually talking about the circle of consultants in the field that I work with that are trying to work on exactly these issues — we try to ask individuals to include captioning for the deaf, where you have a sound clip. It's not that hard. And if you really have some savvy you can get the captioning software right from WGBH; it's very inexpensive and you can do the

captioning right there. Include description video for the blind when you have video clips. That provides narrative.

Again, that's a software package that you can pick up and put in. I've seen individuals who are using their *Sound-Blaster* and doing voice-assist and implementing description video that way.

Include text descriptions for images. Now, this tends to be one of those guidelines that is actually true just because [there are] individuals who don't have access to a GUI browser — graphical user interface browser — but use Links, for example, or perhaps use the W3 browser that was developed by Bill Perry up at Spry. They obviously can't see images with those browsers, so if you don't provide a text description of what that image is an individual is probably just going to get the broken icon up there that just says "image".

Well, that image may be important to what's on the screen. It may not seem like it's important to you, but it is certainly important to the individual who is blind or low-visioned and has no idea why that's sticking up there in the middle of the screen. So provide those text descriptions. We also — again, in line with the browsers and those who are building off-screen viewers — recommend that they provide the option of showing a particular item in a graphic text.

We mention that you should try to provide a complete listing of all URLs that are associated with an image map in a separate link. That way an individual who is blind or low-visioned who can't read or access that image map at least has a way of getting to all of the material and all of the links that are associated with the image map.

This is a critical one: don't use images for text displays. One of the popular things that's going on right now is to throw these up little images that say "new" — that's one of the popular ones.

In fact, I know four or five sites that are positioned solely for the blind who use them and never give thought to the fact that those textual images cannot be read in any way, shape or form by a person who's blind. So if you do put up one of those images, make sure that you use the "alt" parameter and add the text along with it.

Because tables have been included for support since — let me see, I think it is HTML 2.0, certainly in 3.0, and the browsers like Netscape have a support for it — we try to recommend that you provide a simple layout for tables. Now, that's a recommendation that's not always easy to do. Tables are very difficult to display, and obviously they are difficult to code in HTML.

If possible, provide them in an alternative view. For example, people who are blind tend to read things linearly, and if you can create the table in an alternate view so that it is linear it will be easier for them to read and to understand.

Then finally, if you must specialize, if you feel that it is important for you to put up something unique in relation to viewers and data types and context, we also recommend that you provide a common view.

How am I doing on time? It's 11:00. Okay.

Just to kind of round things up... What's the focus of WebABLE? It's really to be a core information repository for people with disabilities and their partners. Users who are blind, visually-impaired, who are deaf, who have disabilities, will have direct access to all the links to all disability and accessibility-related information all the way across the board.

I have received a lot of help and a lot of direction from providers who are interested in the needs of people with disabilities, so I am constantly barraged. I can never keep this site updated fast enough for all of the new sites, and since I do this on my own time I'm usually running up between two or three o'clock in the morning trying to update things. So that will kind of give you some idea.

The folks who are sponsoring this is a small company up in Pelham, New Hampshire, called the Desk Tech Group. They've been fantastic in providing me with all of the support there. It provides links to solution providers and manufacturers and it provides links to research centers and consulting organizations in the context for non-profit organizations.

In the back, again, I mentioned that I left a handout called Access That Text. If you didn't get that, make sure that you do. There is a list on the first couple of pages of several URLs. Because we're running short on time, let me point you right now, if you have those, to some very significant sites that you'll want to go to right away besides WebABLE. You can get to all of them from WebABLE, but here are a couple of them.

The first of all is the NCSA Mosaic Access Project Page. That's about midway down the list there of the WorldWide Web sites, under the research centers and projects. Would you like me to read out the URL? Okay.

The URL automatically is <http://bucky.aa.uic.edu/>. [That last character is a] slash, not backslash. This is where one of the first of our projects for accessibility started, and we're still working with NCSA on accessibility. The chair there for this is [Drew Browning]. Drew is a quadriplegic at NCSA. He's been working with the folks since they were working on developing *Mosaic* back a couple of years ago.

The next is the next one in line — Project Do It at the University of Washington. They are currently looking for young people to give scholarships to for coming to their university to teach them and provide them with high-tech education. They're excellent. The URL there is <http://weber.u.washington.edu/>.

The next two are at the very bottom of that list, under research centers and projects: Trace Research and Development Center, which is <http://www.trace.wisc.edu>. Trace is, in my own opinion, probably the leading research center in the world working on accessibility for people with disabilities across the board, not just on the Internet and the WorldWide Web but totally across the board. I have been working with them for several years now on just a variety of different access things.

They have all kinds of guidelines; HTML guidelines that are up there. The HTML guidelines, by the way, that are available at Trace are in pretty good format here in the back, so you'll want to make sure that you get those.

Then finally, one of the local sites here which is, again, a fantastic site: the WGBH Descriptive Video Service site right here in Boston, <http://www.wgbh.org/pages/dvs/dvshome.html>, and you will see at this site several examples of descriptive video services for the individuals who are blind. You will also be able to find links for close-captioning and how to include that. All of the guidelines for how they are actually doing that on the Internet and the Web are located there.

I apologize for not being able to show you some of the sites. Actually, we're having some server problems and we haven't been able to get to half the ones that I've wanted to show here. But as I mentioned, if you go to WebABLE and if you'd like me to give you that URL again, I will. I think it's actually located right here. Let's see if it's up here... No, it's not on this page. It's www.webable.com/ — you'll find it there.

If you're planning to come to Internet World '96 in the spring, I will be giving presentations there actually showing how to build descriptive video, close-captioning and voice synthesis, and some of the work that's being done for the Internet in accessibility using voice output for the blind. Thank you.

INTERNET VILLAGE COMMUNITY OUTREACH ON-LINE

MODERATOR

Laverna Saunders

Dean of the Library and Instructional & Learning Support, Salem State College

SPEAKER

Lisa Kimball

CEO, Metasystems Design Group, Inc.

Laverna Saunders: My name is Laverna Saunders, and I'm Dean of the Library and Instructional and Learning Support at Salem State College. Salem, as you know, is one of the oldest communities in the United States, and a place where many witches do live. Last night the spirits were restless, and Salem was selected to be a point of presence on the Internet. We're working on a community network. One recommended title was the NetWitch. That hasn't been adopted, but you do see a sense of humor on the Net.

Our next presenter is Dr. Lisa Kimball, who has been co-owner and senior consultant with Metasystems Design Group, Inc. since 1983. She is a specialist in applications and electronic networking and the design of virtual spaces for organizations, teams and on-line communities. She is also a consultant on the implications of new technology for education, business and society. She has extensive experience in facilitating on-line groups and training moderators on multiple networks, using most of the software environments available today.

Her company created the MetaNetwork in 1983 as an electronic community to support a wide variety of individual teams and organizations. Lisa has taken the lead to create and facilitate general discussions as well as special events, performance arts, seminars and interactions with the guest resources for the MetaNetwork, which currently supports more than 6000 accounts. She is also responsible for training, coaching and supporting moderators for private groups.

She has two master's degrees and a doctorate in educational psychology. Her dissertation — and I enjoy the title — was "The Nature of Expertise in Senior Executives — The Role of Systems Thinking."

Dr. Kimball's topic today is "Community Outreach On-line," and I will let her give you her e-mail address and URL at the conclusion of her presentation. Thank you.

Lisa Kimball: Thank you. It's fun to think of being near Salem. Actually, my great, great, however many it is, grandmother was a witch in Salem, who unfortunately was actually hung during that time, sometime long ago. But it's always made me think how perhaps there's a little magic in me or something.

This is a topic which is really near and dear to my heart because in my view the real power and excitement and value of all this networking that we're talking about is not in access to lots of information, although some of my best friends like information. But it actually relates to relationships, and that the thing that the WorldWide Web and Internet does, the thing that it gives us is an additional tool, ways to organize and define and support different kinds of relationships among different groups. The information part, while valuable, is probably going to have less of the revolutionary impact in the long run than the relationship aspect, the community-building aspect. And so that's where the notion of using this tool to do community outreach lies, to build communities using on-line technology is something very important to me.

Now, when I talk about relationships, that's not the kind that I want to focus on, which is what you generally hear in the media. I'm very frustrated with media coverage of the on-line

world. When it's the equivalent of Sweeps Week, we get the inevitable story of pedophiles on-line, people that meet and get married on-line; there's sort of a repertoire of favorite stories along those lines, and what I'm talking about is something I think is much deeper and more important than that. So although we're talking about relationships, we're not talking about that kind of relationship.

The other thing that I want to stress is that in my view the real impact, the important impact of what happens as a result of on-line technology is what happens after you log off. If we're thinking of how we're designing and using environments with these tools, it's not so that we can all go move in and go live in cyberspace, it's so that what's available in cyberspace will give us things that we need, relationships that can support us to enable us to pull the stuff off in the world that we want to pull off. And so that's what I mean by community outreach. Not to go snatch up all the members of the community and haul them on-line to go live there, but rather how to use on-line technology to do things in the community to make things happen whatever your particular interest is, whether it's something like literacy or doing something for the homeless, or helping people who don't have jobs, or providing support for people who have particular kinds of physical or mental disabilities or a whole range of other possible things that you want to have happen out in the community. So that's what we're going to be talking about.

What I'm going to do is talk a little bit about a framework and then I'm going to show some examples of some applications and talk about them. Then I hope that we'll be able to do some interacting together about what might happen.

There are really a couple of different ways that people tend to think about how they're going to use the WorldWide Web to support outreach. One is tell people about the other stuff you're doing, and this currently is maybe 90% of what you see out there. It's basically somebody putting something on-line which is telling people about what we're doing off-line. More powerful, and I see having huge potential but much less use so far, is actually using the Internet-based tools to do something you couldn't do before, not just to tell more people about what you're doing but actually do something different, something that might be qualitatively different. I want to talk about what some of those kinds of things. What are these new options?

One of the things that people find who are moving into this area is that it tends to be something that just sucks up planning/drill kind of processes. We've had a lot of people that we've worked with that put together a committee, like the executive says in this quote, "After six months, I realized that our planning committee was still arguing about the process for deciding which documents were going to be re-packaged in HTML, and we still didn't have a Web site."

I made this slide for a talk that I gave a little while ago, and they still don't have a Web site because they're still so busy trying to figure out what all the policies are going to be and what all the possibilities are and "How are we going to get up to speed about all of that?" that they never got around to doing anything. And this medium is a much more amenable to a cybernetic process than that.

So I hope that one of the things that you'll get out of this morning and the conference in general is the message that the way to go is to do something, then pay attention. Be conscious of what you're doing, learn from what you're doing, and then do something else. One of the things about this medium is that it's much more forgiving than the old paradigm, the information technology applications that we knew about. When we first started working in this area, and that was back in 1983, if people decided to create an applications environment of some kind and do all the programming and so forth, they better be right about exactly how the interface was going to work and what the menu was going to say and what platform it was going to be on and all that kind of stuff, because to change any of that you had to redo the whole thing. It was a major effort.

A lot of times the people in organizations that have a history, the people in your IS department and in your computer services department, very often come from this old paradigm world. They really want to be sure everything's going to be all planned out and exactly right before they even start, because they remember what it was like when you got on-line and said, "I don't like menu item number 6. I want it switched around." That meant days of work. But that's not true in this new Web-based environment. You can do a lot more on the fly, be a lot more iterative and have generative type development. So don't be afraid. Just go for it and do something.

Now, just to give you an idea of some of the kinds of things are people are doing, I created a little hierarchy of what I've seen people doing, a hierarchy of what I think of as the lower-level applications, [and they're] down on the bottom of the slide. By the way, I did hand in master copies of all of these to the CD-ROM maiden, so whatever it is they're going to do to put it together and make it available, it will be available there. If you'd like it sooner, you can leave me a card before you go and I'll send it to you.

Down at the bottom we have, again, what I see as the vast majority of what you see on people's Web sites. It's a different way to distribute the same old stuff. So if you've got a brochure that's about something that you're doing, and I have an example here that I cleverly gave myself some links here somewhere, if you have something that tells about what you're doing and you want to tell more people about it, one of the things that you can do — I don't know why this isn't automatically loading images — maybe I just don't understand Macs, but... There we go. Okay.

Kellogg has an example of a program like this where they've got a lot of stuff that they're up to. For example, one of their community outreach things has to do with total quality schools, and so they've got the stuff that they would send you in the mail, were you to call them up and ask them, and it's available on-line.

That means I got to see it because I wouldn't have thought to ask them for it. It's a good thing to do because it means more people might have access to it as the search tools get better. If I'd been trolling around for total quality schools, I might have found this. So even though I've characterized it as kind of a low level application, it's not that it's not a good thing to do. It's just a fairly basic thing to do.

If we go back to that other slide, that's a perfectly good thing to start with, do that at least if nothing else. You've got stuff that's already on a disk or on somebody's word processor, and it could just as easily be made available somehow on-line. If you're interested later, I did some brainstorming with a group yesterday about some of the ways to pull that off if costs are an issue.

The next level up is where you go beyond, this has a little hypertext in it where you can go to one place or another, but it's possible to... That's a different film. OK. Excuse me. I forgot I wasn't home.

The advantage of hypertext is that it allows you to get people through your information in a much more complex way, and so one of the things that you might think about is some new kinds of information that you didn't used to be able to make available so easily, but now you can.

An example of one of the groups that's done that is a group at Georgetown that has a very interesting site that relates to stuff about medieval history. They're trying to make more presentations out in the world of people that are interested in that kind of thing, and so they've created a very complex, hypertext-based site with a lot of nice graphics on it. It takes a while to get through it, but you'll notice all these things that are underlined and in color are different places you can go, and some of them are at other universities. What they did is pull together in a hypertext way a lot of very interesting information. This is a new kind of program they can do

now, be a clearing house or a conduit, and that's another level of the kind of thing that you can do.

The next level up is to go beyond simply doing the same information but in a different way of organization. We might as well see the blimp, as long as we're going to Goodyear. Goodyear has a program where they're trying to help you figure out what kind of tires you have. Now, obviously, they have a motive for doing that. That's a commercial motive. There's the blimp. But you can also find out things like driving tips. This is an example of the basic hypertext brochure kind of thing. But what they also have is the tire selector, so they're using the basic interactive quality of the Web which is the ability to do forms. You can fill in stuff about what kind of car you have and what kind of tires you have and things about what you care about, whether you care about the looks or whether you care about safety or whether you care about performance. And after you fill all that out they bring to you a customized piece of information about what kind of Goodyear tires are the right ones for your car. If you fill in your zip code they'll tell you where you can go buy some.

Although this a commercial application it's an example of a way of giving information that could also be very useful for a lot of people who are doing more community oriented applications.

For example you could, as a mother, fill out something which gave information about when you needed child care and how old your kids were and what some other aspects of your life were all about, and the database could give you back some options for what kinds of programs were available in your community and who to call to get them. Instead of my having to be the searcher and trolling all through that, we're using the power of the computer to give that information back to me. That requires an investment on the front end on the part of the organization that's sponsoring it, but it's a tremendously useful thing for people out there.

You'll notice Meckler has done something similar. They've got a questionnaire-type thing on their page, if you've looked at the one about the conference where you get to say what kind of computer and stuff that you have and what sorts of things you're interested in.

Now, what I think of as a higher level of doing an Internet-based communication strategy is something where you're actually trying to bring people together into some kind of community.

An example of this is the *Hungry Mind Review*, which is a bookstore publication in the Twin Cities in Minnesota. It has developed a site where you can do all the stuff you'd expect to do, read through things and check out stuff. You can also fill out questionnaires, look at back issues, find out what's going on, and you can do things like participate in discussions. What they make you do is sign up for being a participant and once you've done that you can get into threads, which might be about a particular book. They might be about political topics, all kinds of things. They tell you about who's coming to the review next and who's coming to the bookstore to talk, all those kinds of things. They've gone beyond simply providing information about their bookstore and they're actually now, because they involve interactive on-line discussions, trying to create a community around that bookstore.

What's interesting is because it's a Webbed community, it's not just the people who are nearby enough to come by and come in and come to the author lectures. it's anybody who can float off to their Web site. So it's a very interesting kind of application.

Now this is much more complicated than just the simple, "put your brochure up on the Web by using one of those cool tools that people have on the show floor that take a document and zip it up and give it some colors and icons and things." As this cartoon says, "Granted, it doesn't have the versatility of our other models, but most people find it much easier to play."

The point I'm making here is you get what you pay for in terms of the human resources and consciousness resources you put into stuff. It's more complicated and harder to do these

more complex community outreach applications, but the payoff is much bigger, probably just like a grand piano would give us a little more than this in the long run.

This is what I call a “purpose matrix.” It’s a way that you might think about how to figure out your strategy for designing some good on-line applications. Across the top — and this is not a dichotomous kind of a dimension — four-box models is what you get in the template program in my word processor anyway. Think of that as a continuum from applications where mainly what you want to do is disseminate information out; from the point of the user, they’re scanning around to get information. On the other end of the continuum we have situations where what you want to do is make some action happen. You want to implement a program. You want to tantalize action, get people to do things. Probably you suspected my bias already that getting people to do things is going to have a greater impact in the world in the long run than just giving people information. So far there’s not a lot of evidence that simply giving people information, for example about why it’s important to recycle, or why they should stop smoking and so forth, doesn’t itself create change in behavior, and we need something more to do that.

And down the left-hand side of the continuum we have people that I’m calling “known constituents,” people that are either members of the organization, clients of the organization, or obvious fellow traveler constituents that you know about on one end of the continuum. On the other end of the continuum are this unknown public, the surfers, the whoever’s just out there that might be getting stuff.

For organizations, the smart strategy needs to be comprehensive and include activities and things that you might be doing that would fit into all of these boxes. But I do have my bias about which ones are the highest leverage and give the most payback.

If you look at the upper left-hand corner, if you’re just trying to get information out to people that you know, there’s the on-line version of providing them with newsletters. One of the nice things about on-line is you can provide them with back issues very easily and at low costs instead of having to print them out and all that. Put them up there once, and there they are.

You might just be giving them information about who to contact for various stuff, clippings services, those kinds of things.

For your unknown public, that’s where your on-line brochure goes or your catalog of information, things that “shoot a gun up in the air and hope a duck flies by” kind of thing. You don’t really know who’s out there or what they’re going to be able to do, but you offer them something.

Over on the lower right, if you have an unknown public, but you want to call them to action, that’s where you want to do something like weather campaigns or they might be able to do on-line registration.

As an example, The Children’s Defense Fund has a thing that allows you to actually write a letter to a member of Congress. They give you the form and everything right there for when there’s not so much Internet traffic that you have to wait around a long time, but we’re all waiting for that to come up. This is where you could do questionnaires, gather information in as well as get information out, do these higher level kinds of things.

That upper-right box, that’s the box after my own heart, because that’s really where you get stuff that is more than you would expect to get out of these other strategies. This is where you get the community building, doing something actually in the real world. This is where you could have a task force and they could use the Internet to get to a place where they could work; and this task force, instead of only consisting of people that have time to get wherever it is they would need to get on a Wednesday night, consists of anybody in the organization, no matter where they are, that needs to get around.

You might have a focus group to bring them together to talk about stuff that you're doing and to provide feedback and work on it. Again, you're not limited now to just the ones that would let you go specifically to a particular place and time.

Also, this is where I would put special events. This Georgetown group just had a conference on cultural friction. There were amazing things in this for those of you who are into esoterica; they posted papers here. Let's say I'm interested in this paper, the practice of medieval cultural studies, and I've read this and now I want to make a comment on it. First I can look at comments other people made on it. (Except for not right there I can't. Welcome to the wonderful world of the Internet... Let's see if I can do this one. Well, I'm not an academic. Those of you who are academics probably get this more, but there was very "dancing on the head of a pin" type stuff here.)

Here are some examples of comments. I can look and see "What did these other people have to say about this paper?" Now I can say what I have to say about the paper. What they've done is more than simply broadcast information about the conference, "We're going to have one and here's what it's about." They've gone a step beyond in actually providing content for those of us who couldn't be there. On top of that they've created a community around this, where people that are interested in this kind of stuff, and I think it's really good that now they have some help to find each other, are able to get on and make comments and look and participate. It's not just the recipients of information.

The next version of this same kind of way of looking at things is another four-box model. I admit to being an organization development type, and there's some thought that we see the world in four-box models. This is another version that shows some of the specific Internet tools that people are using in these different boxes. The labels of the squares are slightly different, but it's the same idea.

Disseminating information to teams or specific organizations is where, obviously, e-mail and your moderated mailing lists and those kinds of things can make a difference, and so on around. One of the harder ones to pin down is when you have a public group and you're trying to call them to action. So far there haven't been a lot of really good tools for that. People have tried to do electronic town meetings for example, and we've been involved in the Vice President's Task Force on re-inventing government and some of the kinds of things they've been trying to do. Let's see by chance if we can get there.

They have been very frustrated with the problem of getting comments that make sense to use. If you get thousands of e-mail messages in from the field, that's not very processed, and you can't really do much with it. This mass scaling-up of input is a problem, and there aren't a lot of really good software tools to process that kind of thing. But electronic conferencing, is what we focus on, and other groupware tools are very good for that upper-weight project.

Again, if you're trying to do a strategy that includes all these different boxes, it can feel a little bit like you've bit a little more than you meant to chew, as this frog found out. But it's worth it. It's really worth it to be thinking of applications, not in term of "There are mail lists. What do I do with the mail lists?" or "There are Home Pages. What do I do with a Home Page?" but to think rather in terms of "What is the purpose of what we're trying to do? What is it we've always wanted to do in terms of community outreach that we haven't been able to do, but maybe we can use these tools to do?" so that your applications are really driven by things that are aligned with the goals and values of the organization, not "Whoopee-do, there's new stuff" and so we've got to get going with it.

We get a lot of calls from people where a typical call would be, "We've got to get some of this Internet stuff." And then, "Well, exactly what do you mean by stuff?" "Well, I don't know. The board met and they said we've got to do this Internet thing and I'm the one who's got to figure out how we're going to do that." That poor person often has no direction because

the board is not capable of giving any, to help them figure out “What does that mean? Are we doing this so that we can get more members? Are we doing this to provide value-added services to the members we already have? Are we doing this because we’ve had a financial cutback in our budget, so now we can’t distribute as much paper, so we’re going to do it another way? What is our purpose? What are we trying to achieve?” And it’s very important to drive applications from that direction.

This is the picture of the organizations that we all grew up in and that we know about, the conventional organization. Very often a lot of community service programs or community outreach programs start from an organization that’s kind of in the structure. One of the things that’s sometimes a challenge for people who want to do this kind of work using these tools is that the people who are in charge of the computers are the consultants that have been brought in to deal with the computers or one of those boxes or relating to one of those boxes, and you get some turf problems.

One of the things that’s neat about this technology is that there are some good strategies for escaping that. By nature it’s distributed and flexible, so a lot of organizations have found they needed to she said wrest control out of that.

Where you really want to go is [to the point where you are] thinking of either your organization or your project as something that looks more like this [diagram on the screen]; without worrying so much about what the words are, you can use the on-line or virtual environment to create groups of individuals, groups of projects that both go across functions within your own organization and make partnerships with other organizations.

One of the things that this technology allows you to do very well, and it’s really an important aspect of community outreach, is partnering. This picture here could be a picture of your Web site and the Web sites of two or three of your community corporate sponsors or local community college pieces of the program or sources from funders or other related programs. You could be using Internet or Web-based technology to link all those things up, and that could be a very good use of the tool.

Before I open it up to questions, just to see one more time if I can look at a couple of these things, let’s go back and see if we can get Children’s Defense Fund — just some more examples. The Children’s Defense Fund, as you probably know about the organization, is obviously focused on children, so they’ve got a Web site that shows children. And here’s their urgent e-mail from the president. They don’t want you to just look at the information about everything that’s bad or problematic going on with the bills in Congress and so forth; they want you to actually do something, so they’re in that call-to-action or implementation box. You can click right here.

So now I can send. It automatically gives me a form and blah, blah, blah I can say whatever I want to the president. I can even quote a document that’s one of the documents from this Home Page, etc., etc. What they’ve enabled me to do is not wait until later to go do what they’re telling me to do. They’ve created a space right on-line where I can do it and I might be more able to do it that way.

For those of you who’ve done letter-based campaign kinds of things, one of the things that’s really interesting about doing it via this on-line technology is that the form letter kind of thing starts piling up and just going right by a lot of members of Congress, because they get a lot of them. But if you can provide text that I can download into my own word processor and then I can customize it by adding some personalization and things about me and so forth, that can end up being a much more powerful letter. So that’s a very interesting thing.

I don’t know what that’s going to give me. That’s an example of getting people to actually do things on-line.

The National Performance Review, as you may recall, is where Vice President Gore set up an interagency project to try and generate ideas for what government organizations could do to change the way they operated in the way that everybody seemed to want. But because it was interagency, there was no single place where the people from all the different agencies could gather. After the project was over, which was September 6th, now two years ago, everybody went back to their agency, back to their own internal e-mail systems — which are many and varied within the government — and then in order for them to have a continuing place to be a community and to do a discussion, they created this environment on-line.

One of the things that was neat about it is that because it's a Web-based environment it means that you don't have to be part of the agriculture department or the any particular agency to participate in it. It means anybody who is motivated to and wants to get involved in this and join up and so forth can do it, without violating any of those security type heebie-jeebies that people in the sub-basements of many government agencies have, who really don't want the public signing into their proprietary computer because of whatever they're doing in there that they don't want us to see. The ability to create a conversation environment where people can get on and talk about what they need to talk about in a safe neutral virtual space gave them something that they wouldn't have had otherwise.

There have been a number of applications like this out there where maybe several organizations working together on a project, say jointly working on a community project, and they all have this thing where they don't really want it to be in any one of the organizations bailiwicks, because that's threatening and it gets to be a turf thing: Who owns it?

One of the great things about the Web is you can really create a collaborative multi-partner kind of situation where they can keep their information on their computer and we can have our information on our computer. We can get to both things, but it's nobody's thing that just they own. So that's an example of doing that kind of project.

What this is is a list of the topics that these folks have been discussing. Let's look at a recent one to give you an idea. The budget battle, the topic du jour, this one I happen to know. That's a person from the Internal Revenue Service. This is a person from a personnel agency. Brad is somebody who used to work for the government but is now outside as an economist and accountant. They're all able to have a conversation. Dave is a local government official from Pennsylvania and so on and so on. It gives you a way to have a group of people from different places gather together to have a conversation they need to have, whatever that is.

Let's look at another example now that we're working here.

ArtsWire is a coalition of arts organizations. There are now about 600-some-odd arts organizations. They're everything from very big ones, like the American Craft Council, to much smaller ones like the Native American Craft; I think they're Craft Association or Craft Club of Eastern Wyoming. We have a whole range, some of which may have only two staff people. Of course, being artists they're somewhat graphic-intensive, so we all get to watch paint dry while we're waiting for the graphics to come up. But one of the things that they've found, again, is that each one of these organizations sometimes even competes for grants with each other. So to form a coalition of this type of group, it was very hard to find a safe neutral space. The on-line space gave them a creative place where multiple organizations could put their stuff under one umbrella; you have the one-stop-shopping aspect of things. At the same time, it allows them to have multiple kinds of discussions.

Now here's their sort of front door-type of thing, and one interesting current thing that's going on is there's a big conference in New York, which was on "Cultural Diversity." They had a team of people at that conference providing reports and opportunities to comment to the people that were on-line about that conference. This is a very nice kind of outreach application. There's no new conference activity, because I already saw what was there. These

are for example, you can see what the comments were about, who was speaking, a call for a cultural contract with America and so forth.

One of the advantages of having this on-line for these multiple organizations is that a lot of them can just suck some of this material off-line and put it in their own newsletters and other media. It's not just being on-line and never getting off it, it's using the on-line as a point for all the interesting things that people might want.

Let's just take a look and see what a cultural contract with America would be like. The Caribbean Cultural Center, which was the sponsor of this conference, they were sort of like a White Paper... and there it all is. We could take this paper and we could make it part of our discussion group at church, or we could bring it into our classroom, or we could print it out and talk about it over Thanksgiving, or we could have a conversation about it on-line. But the fact that it's easy to get to and in a common place is what makes it worthwhile for this group.

Let's see if there are any other examples. I want to show you one more thing.

I like to go to conferences and talk about the ones that I've gone to, so some of you may, if you're in the library community, be familiar with Steve Sizzler and the Apple Library of Tomorrow project. He has, for the last several years, had a conference called "Ties that Bind," which is about community networking. The one last May I happened to have gone to, and I wrote up a lot of the kinds of things that went on there and I put them on-line. And again, because they're on the Web, it meant that a lot of people that were working within free networks or in libraries or in other places could simply link to this site and be able to provide all the information there. It's an outreach and "small amount of work for a large amount of payoff" kind of thing. This was very good.

I also did a similar kind of thing with the National Education Computing Conference, where there are a lot of interesting sessions, and just so nobody would miss it I even covered the parties so that you could really get the feel for what it was like to be there even if you couldn't be there.

Again, one of the neat things that's growing is the multimedia capabilities of the Web, that allow you to do stuff, not only writing the text, but — I would have brought the really cool little Casio digital camera that we have that takes 96 pictures with no film — you just capture all the stuff, dump it into the computer, and it's automatically in a form that could be posted on-line. It's great for being able to show old pictures of neat folks, so that they can get the sense of who people are, and it's also a neat way to capture what's going on at a conference for people that aren't there.

This is an example of one of the pictures that we just took in the office and popped up on-line. You can do a lot of things with this. If you have multiple groups or have people having regional meetings, just imagine — you could just take a picture of what they wrote on the flipchart or on the whiteboard and pop it up on-line digitally this way, and it's a lot cheaper than those shared whiteboard type technologies. There are a lot of interesting possibilities.

This actually, now I think of it, wasn't taken with a Casio camera, but was done with something called Snappy, which is a product that you can get to go with a regular video camera. You might have to take pictures of your kids or grandchildren, and what it does is let you capture a frame and it makes it into digital form and just sticks it up. It has software that goes with it for Mac or Windows. That shows you what you could do with that.

The bottom line message is, "It's the relationship, stupid," to use the thing from the last campaign. It's really more about "How are you going to catalyze relationships in your community?" What kind of information are you going to push out at people?" You really want to find ways to use this technology to help you do things that you've always wanted to do. Wouldn't it be great if we could get everybody co-planning the conference with us instead of

just pretending that we're getting input, so that you're doing something different and not just doing the same old thing in this new medium.

But rather than not do anything, at least do the same old thing in the new medium and get going on that and get a feel for it.

My recommendation is, if you haven't started exploring this and its applications for your organization yet, one of the best strategies is to create what I call a "scout team" that would be a group of people from maybe both inside and outside the organization, whatever is appropriate, including your key people inside, and perhaps some constituents or customers or the members, to be a group that has full Internet access. They can go out there and look at what other people are doing, get experience and be in some kind of interactive communication tool use with each other, to talk about what's going on out there that we ought to be thinking about, so that you really have that base of experience.

If at all possible, don't get yourselves captured by the consultants, even though I am one. One of the things that I've seen a lot of, and particularly nonprofit organizations suffer from is, because people feel that they don't know a lot about computers or they feel kind of one-down about the knowledge, is that they allow fast-talking, whoopee-do, techno-nerd, wire-head types to come in and with a lot of mumbo jumbo to scare them into either thinking, "Oh, God. Maybe next year we can get into this..." so they don't even want to do anything, or they're looking at very comprehensive, very high-cost solutions which seem like a very big deal to have to put together all at once. What you really want is to find ways to get experience, get your toe in the water, try something easy and cheap, learn from that and do the next thing. The most important aspect of it is your knowledge of what it is you want to pull off, what needs to happen in the world that's not happening now, which is the reason for this community outreach program. You actually have a lot more knowledge than a consultant could ever have.

[Tape change]

Lisa Kimball: And play with the tools so that you can get a feel for what they can do for you in that regard.

So I think we have a couple minutes before everyone starts to dash if you have any questions or would like to make a comment. Anybody?

M: [inaudible]

Lisa Kimball: This particular one is based on something called [*Web Caucus*], which is a computer conferencing product that we have. And if you'd like to know more about it, you can give me your card or call from the number on the brochure. I'd be happy to let you play with it.

Other questions?

M: What are the demographics these days? How many people have browsers [inaudible] and what's the projection for growth in the next ten years, [inaudible]?

Lisa Kimball: Right. That's a good point. Well, there's a lot. It's happily changing and growing fast. One of the things that you might consider is that it is possible to get to a lot of this information that we've been looking at. Even using a text-based browser like *Lynx*. which you can use at 2400 baud with a 286 computer, you get all the stuff. You can't see the pretty pictures and it's not as easy because it's not as click and point, but it at least is accessible at that level. The strategy of the Internet service providers is to try and distribute a lot of software and get a lot of people on. Getting the software part hasn't been very difficult, and depending on

your community there are things available like freenets or local city nets or library sponsored activities that can get people on.

One of the things that we forget in community applications — and we worked on a couple, we worked on one in Santa Monica, California and we're now working on one in Salem, Oregon — one of the things about that is that every single person doesn't have to have their own computer in order to take advantage of something like this if you provide some public access, either from libraries — community precincts in the police department is one of the things Santa Monica did — and schools and so forth. If I get on-line on Wednesday and talk about some stuff, and you get on-line on Thursday and talk about some stuff, we're still having a very valuable asynchronous communication even though we're not accessing that from our own personal computer. So I think that's a very important point.

And I think in the session earlier — which I didn't attend, but I scarfed up the materials — [they said] the other important consideration is that there are people for whom do we interfaces that are not ideal, and we need to always be thinking of making sure that what we're doing is accessible by those people as well as by the click and point. The ease of use doesn't necessarily mean click and point. So that's a good point.

Other questions or comments?

W: Do you have any idea how many [inaudible] on an average?

Lisa Kimball: I don't, but I'm sure that information is available because you're able to track that kind of thing. That's one of the things in the session yesterday, and I think probably some other people pointed out — that one thing is hits, how many people show up. But in order to really capture information about what's going on and who's using your service you need to use some of the same kind of strategies you would in other PR or outreach things, which is to find a way where they tell you something about themselves. They fill out a form to get a piece of information, they sign up for a contest, so that they're saying, "Here's who I am and here's what I'm doing here." You know, like putting your business card in the fishbowl at the local restaurant. You need to do an on-line equivalent of that to really get information about the quality of the hits or the interaction that you're getting. You can find numerical numbers wherever the host is, and they can produce how many people showed up and they clicked on this or that.

W: I have a question in the commercial on-line services about partnering [inaudible].

Lisa Kimball: Some of those things do happen on on-line services, big on-line services, and we're doing a big project now with PBS, which is a big distributed network. Of course, they have all those local stations, and contrary to what Newt thinks public broadcasting is a very grass roots, local phenomenon. So some of that goes on.

In general, one of my beefs with the big commercial on-line services is that their idea about community outreach is not always the same as my idea, and that they're really looking for bodies showing up so that they can convince a sponsor that there's enough bodies showing up that it's worth paying the cost. Those of us that do this kind of thing know that a small group of dedicated, very focused people might get something very important done. But it's hard to talk to America Online about an application for a dozen people. That's just not what they're all about. And happily in the Internet world, again, it will be interesting to see what the future will be. I think those big commercial on-line services are likely to become more and more sort of consumer product-oriented because it's possible for a relatively small organization to have a

host hooked up to the Internet and do something without needing to go through that intermediary.

In the old days we needed those big intermediaries to get everyone on the “highway.” Now more and more the root to the highway can be very local and low-cost, and so once they’re on the highway they can go anywhere. And that service those big services used to provide us is no longer as critical, I think.

Way in the back.

M: [inaudible]

Lisa Kimball: Neat idea. Yes, one thing you might think about if you’re a small non-profit or community organization is that one of the things your corporate friend, sponsors, contributors, etc., could do for you very easily is provide you some space for presence on the Web. If they already have a Web site going, and they’re already paying the telco costs, putting your pages on there really doesn’t cost very much to them. So if it’s the kind of thing that you might ask for — services in kind — and that might be good to do, then check it out. Then do something else, because you could get experience and because all the files could then be moved when you were ready to do your own thing, having had that pilot experience, and then that wouldn’t all be just sunk costs. You could easily pour the bowl in a portable way, move it to another environment.

You’ll soon discover that I’m not the techie in our bunch. I don’t even use self-service gas, so actually how it works, I can’t tell you. I know a number of organizations where they’ve got one piece of the server, like an NT server outside the firewall, which is accessible by people outside the organization to do various things like their files of that type. That can be networked through the firewall to other stuff, so that people can’t get from the outside past the firewall, but you can go the other way. There are probably people in the other room over there that understand exactly how to make that work, which I don’t. But there’s probably a solution like that out there somewhere.

M:[inaudible]

Lisa Kimball: That’s a really good point. One of the things that’s so cool about this technology is that there’s greatly more diversity than there used to be in who can be providing the pieces in some or all of these various services. It’s really good to look beyond what you’re seeing on the nightly news and see if you can find something more.

One thing that has worked well for a lot of community organizations is to put together a group of people from the community to be part of the scout team, like I mentioned before. One of the things they could [inaudible] about is what’s out there that we may not know about. Maybe there’s a statewide network; maybe there’s an entrepreneur as part of start-up who would like to have some applications that he or she could talk about, and maybe you could be one of those and do some kind of little quid pro quo. Maybe there’s a corporate partner. Maybe somebody’s got a sixteen year-old with time on their hands — there are a lot of different ways to do it.

The key thing is to go out there and not be a person who is saying, “Well, I don’t know anything, so I have to get somebody else.” You know, you can learn about this the way that you learn about other things. Vic Sussman said yesterday, and I was cheering “Yeah!” in the back, that it’s funny how this computer technology, even network technology, is the kind of thing that people are willing to admit that they’re dumb about. We wouldn’t admit we were dumb about other things. It’s not that complicated; even I’ve been able to do a lot of this and I have no idea how it actually works, anymore than I know how my car works. I just know how to drive it

some place that I need to go. And if I need something to go on in the middle, I do the equivalent of going to Jiffy Lube. In my office, I go, "Scott, help." You need to find somebody like that to help you. But be sure that what's driving it is what you want to do, not what techies are telling you you ought to do.

Somebody in the middle had another one.

W: [inaudible] fundraising?

Lisa Kimball: Fundraising is an important thing. You mean in terms of how people have strategized to fund raise on the Net? Well, one thing about the Net which is kind of interesting is that you can put credit for people on quite easily, so that's one thing that people have done. For example, when a corporate friend has let them have some space or something else, you can have a line on the bottom that says "Web space and other resources compliments of," you know, sort of a cyberspace version of the bowling shirt thing. That way you can give people credit. Generally, people that are into this stuff tend to be proselytizers, so a lot of times they enjoy the process of helping.

The hardest thing about fundraising right now is that people have not developed very sophisticated evaluation strategies for how you communicate to a funder that this has been something worthwhile and important. ArtsWire, for example, had a lot of grant support funding from the New York Foundation for the Arts and the National Ballet for the Arts has went into.

How do we demonstrate? I'll hype my own favorite technology, but what having the interactive part does for you is it allows you to create the kind of testimonial/anecdotal material that can be very rich. So if you have people on-line telling stories about how I have this problem, and I couldn't figure out this or that...

Iris is a network of teachers. I couldn't figure out how to incorporate the new math standards into my classroom because I never had statistics myself. Then I got on-line on the Net, and I work with other teachers and I got this information, and as a result the 27 kids in my fifth grade class are now doing the work.

You've got really good, rich material, and with that material you can tell quite a good story to a funder. Having that aspect to capture that can be helpful. That's probably the biggest missing piece I think for fundraising. "What is it I'm going to tell people is going to happen as a result of them giving me money to do this?" and then "How am I going to prove that it did happen?"

So that's another good arena for the academics out there, to help us out with some new tools. John's going to do that. I know in the audience you've already solved that.

M: [inaudible]

Lisa Kimball: Great.

Any other questions, comments? All right. Well, thank you. I enjoyed being here. If you have any more questions, come on up.

INTERNET VILLAGE
EDUCATION AND LONG-DISTANCE LEARNING /
EDUCATIONAL TREASURES ON THE INTERNET

MODERATOR

Laverna Saunders

Dean of the Library and Instructional & Learning Support, Salem State College

SPEAKER

Gregory Giagnocavo

Consultant and Writer, Wentworth Worldwide Media

Laverna Saunders: Welcome again. This is the Internet Village track. I hope all of you picked up a brochure, *Classroom Connect*. They're on the literature table at the back of the room.

M: We can't hear you.

Laverna Saunders: (OK, now can you hear me?) Our next presenter is Gregory Giagnocavo, an internationally recognized Internet speaker, author, and Internet consultant. Gregory has played a major role in bringing the myriad educational resources of the Internet into elementary, middle and high schools. As director of Wentworth Worldwide Media's Classroom Connect Product Development Group, he has an in-depth understanding of the enormous educational potential of the Internet. He is much in demand as the speaker at local, national, and Internet educational technology meetings, and is known for his ability to capture and hold audience interest and giving informed forecasts of new applications and educational opportunities on the Internet. I believe if you are in the exhibit area and you see the booth, there are a number of his books on display and you can order them.

In addition to the *Classroom Connect* newsletter for K-12 educators, he is the author of several books, including *Net Power*, *Resource Guide to Online Computer Services*, *The Educator's Internet Companion*, *The Educator's WorldWide Web Tour Guide*, and the *All in One Internet Kit*. He's currently working on a new project, *The Educator's Funding Guide*. His e-mail address is connect@wentworth.com, and his URL is <http://www.wentworth.com>. So now I'd like to introduce Gregory Giagnocavo.

Gregory Giagnocavo: Can everyone see all right? I know that some of you are on the wings there. If you'd like to move towards the center, as convenient, that would be great.

My name is Greg Giagnocavo, and we're with Classroom Connect. This presentation is really to get you excited about the different possibilities of using Web sites in the classroom or in the teaching experience. Many people usually exclaim, as they flip through our books when we explain the Internet, "Oh, I didn't know that was on the Net" or "Oh, I didn't know that, isn't that interesting," and "I didn't know that was on the Internet." And so that's sort of what I could have called this, "I didn't know that was on the Internet."

We'll go for about 45 minutes and have a few minutes for questions. If we go along and you have a question about something, I'll try to take it, but if I ignore you it's nothing personal, we'll just keep moving. And we're basically going to go through and have sort of a bit of "eye candy," as it's called, and see what's on the Internet for schools.

Every URL that I refer to, every screen that's up here, is in the hand-out that has been given to you. There's an Educator's Internet Resource Card, it's called. It's yellow, and it has several hundred sites on it. These are in there, and they're marked on there.

At our booth, as Laverna mentioned, we have a number of other products that you might be interested in. So educational treasures on the Worldwide Web, we're going to take a fast tour through some of these, and we'll slow down a little bit later on. The one that is really interesting is FedWorld.

FedWorld — regardless of what you think of the current administration, this administration is throwing tens of millions of dollars into putting on government information that really we paid for already, but we're being asked in the last, say, ten or twelve years to pay for again, sometimes up to \$200 an hour if you're at Mead Data Central, or Lexis and so on. We are paying for the same information all over again that's now being ported to the WorldWide Web so you can get to it anywhere in the world with a simple browser. Over 130 databases are on FedWorld: Census, Department of Commerce, and so on. We'll take a look at some of those later on as well.

The Department of the Treasury is on the Internet, and you can see that we have a Who's Who in the Department of the Treasury; and in case you really wanted to see his picture, the current head of these departments is on Treasury Bureaus, Treasury Services, What's New. One of the things that you'll find from a lot of these sites is they might start off seeming sort of perfunctory, sort of telling you this is the Treasury Department, this is what they do, and that's a little bit boring sometimes if you're not really interested in that particular aspect. However, if you'll take a little time and you'll dig a little bit deeper, a lot of times you'll find lesson plans that have to do with this site. And if you dig deeper and deeper, you'll find lesson plans, you'll find stories, you'll find personal glimpses and so on.

The Webmaster that designed this site's first charge was to get it on-line, and they've done that. But as they've had more time and it's seasoned — it's been now six months for many of these sites, some up to a year old — you're going to find more and more interesting things buried in these sites. So I encourage you, if you find something that's even of a little bit of interest to you, dig a little bit deeper and you'll find more and more interesting things as you dig deeper into the site. And of course they're free for downloading and reproducing in most cases to use in your classroom or in your experiences.

NASA has many, many sites on-line. This particular one is, I guess, is one of the Home Pages that leads you deeper and deeper into what might even be described as other Web sites. It's like a labyrinth, the way they have it set up. Everything that you see, of course — how many of you are on the Internet now and are using a graphical WorldWide Web browser? Okay, great. We've got a good crowd for that. Most of you are, so I won't explain some of the other details of how to use a Web browser. I've been in sessions, though, where we've had teachers that smiled and nodded enthusiastically, and said it was great. And they said, "By the way, do I need a modem to get on the WorldWide Web?" So, you know, we have all different levels of experience.

I was surprised to find, when I was putting together an article recently, that this NASA Center Map actually describes many more NASA centers than I even knew existed, anywhere from the Goddard Institute for Space Studies in New York to — there's another Goddard Center, it's not even on this map. There's a Jet Propulsion Center, Jobs in Space Center. Everybody knows the Kennedy Space Center, but you may not have known about these others.

And when you click on these, take it to WebSite Central and then deeper and deeper, you'll find all kinds of interesting things to use in the classroom or to use in studies, for developing lesson plans or developing schematic units that would range anywhere from the actual astronaut reports that they file after every space shuttle mission. They actually file a report that says what happened to all these experiments. They read about how they're going to go out in outer space and maybe try to grow crystals, or develop a new method for analyzing

something in weightlessness. And they have to file a complete report. Well, those reports are available in most cases.

You can download space patches, every patch. There's a crest that's designed for every space shuttle mission, and you can download all of those. There are lots of interesting things, including lesson plans on-line as well for every grade and every interest level. There was one I downloaded from a space shuttle report; they had taken some bees into outer space, so I thought, "Well, what's so scientific about that?" And they were trying to see whether bees can fly in outer space, and if they fly, do they still do directional dancing, and what happens when they're in weightlessness? They found that when they go into outer space — this is a report now that I'm reading, it's about 30 pages long — and it says that when they got the bees they seemed to be a little lethargic, and they moved a little bit, and they seemed to cling to the side of the box. And I'm thinking, well, whatever. And at the end it said something interesting, "However, all the subjects died." And so I thought, "Well, maybe that has something to do with, I don't know, being weightless."

But if you dig deeper into the report, this is what they do with our government money; they not only took these bees up, they died, and I guess they did little mini-autopsies on them. They found out that the reason the bees died is that the astronauts had forgotten to take any food along, and they simply starved to death in outer space. So it really had nothing to do with weightlessness, and they just simply starved.

[Library of Congress] is a gargantuan site. There's so much here you'd spend an hour just visiting this site. Again, there are lesson plans, and if you dig deeper there are branches off into many related areas, and lots of exhibits, and they have many, many graphic exhibits. So there's many traveling exhibits that end up at the Library of Congress, and you can actually view them on-line. You can download them, remember, and save them to your hard disk, actually build units around using the information you find on-line to put into a multimedia presentation such as *HyperCard*, or *HyperStudio*, or any of the other *PowerPoint* different presentations, and actually take that presentation when you're done and post it back out on the Net again as sort of an iterative process in learning.

How many of you are in K-12 education as opposed to higher education? Okay, about half the crowd. All right.

UUNet Public Library is pretty interesting. So what you're going to see — I'll point this out as far as a trend — you're going to see more and more robust sites. In the very early days last summer you saw sites about things put up by people; now we're seeing actual commercial ventures, still free, and we're marrying the commercial ventures with the education.

Traditionally commerce and education have seemed to have been at different corners of the ring, and they didn't know where the common meeting ground has been. Suspicions arose. Education always seemed to be a little suspicious of business interests when it got too close to education, and I think that we're finding on the Internet that you really have a common meeting ground, where we meet, I think, quite well. And you're having a lot of information being put out for the benefit of education, and yet businesses feel they're getting paid from their end for it, and education doesn't have to pay for it.

And you'll see a lot of sites being put up. I think they'll be more rich, more interactive, and they'll be sponsored by other corporations that believe it's in their best interest to put sponsorship on some of these sites, as in the Public Library. As of recently it hasn't been sponsored yet, but it's very rich, very robust, almost like a homework helper with thousands and thousands of links buried deeper into this site.

[Here's a site with] famous paintings on-line, and this site is obviously called "Web Museum." You can actually click on these links and actually find out biographical information about the artists. [There's] lots and lots of history associated, and, many times there are links

to other things that happened in history around that time. So if you're teaching in a K-12 environment or if you're learning in that environment, you have cross-curriculum going on here. You might be looking at something in art, discussing things about the author like biographical information, or linking to the country and then linking to historical events that happened around that time. And you have sort of a cross-curriculum learning adventure going on.

Here we click deeper into it [and find] bio's, pictures, and information about that particular period. And clicking on these smaller thumbnail sketches will bring up the full sculpture in this case.

The Smithsonian has changed their Page a couple of times. I will give them credit for being one of the first to put a professional Webmaster in, and they have a very, very robust site. I'll use that word robust a lot. You probably won't hear it the rest of the day after this session but robust means there's interactivity, it's really rich in the content areas, very creative in the way they present information, and very, very useful.

I took my family down just after I did this presentation, as I prepared it, and it just so happened we were going to spend the weekend down there as I was doing another presentation for AFT. And lo and behold, there's the Smithsonian. I didn't know there were so many affiliated sites affiliated with the Smithsonian. But [if you] print out a map, take it with you, find out the hours of operation and when you can get in there and the history of the building, you can find out about people that maybe designed that building or were instrumental in founding it a long time ago and you can print all that information out. And you can have cross-curriculum learning, as well as the practical aspects of finding out the things about visiting the museum.

Places, people, activities, perspectives, resources, products. I spoke to the gentleman that's in charge of this project. Actually this year — and you'll see if you've been out on the floor — some of the multimedia players [are] coming along. *HotJava* [and] Macromedia players are being built into the Netscape [products] and some of the Adobe things. They're actually going to have, at the Smithsonian when you go there, the interactive projects and the exhibitions, the things that you can actually touch a button and make it happen, and the [Vandagraf] generator where your hair flies straight up in the air. They're actually going to put those on-line, so you'll have on-line interactive exhibits, as if you were actually there as close as you can be, cyberspace-wise.

So you'll be able to activate different exhibits and see things fly around, your hair fly up and different things like that. They'll have those built into the site. Again, greater interactivity which helps people not only stay interested in a site but it makes it more valuable, more of a learning experience, with lesson plans and other helps in the classroom and with things for putting together semantic units buried deeper into the site of the Smithsonian.

Here's what I was referring to: a map of the mall, all of the different affiliated centers and institutes.

[Here's an area called] Paleontology Without Walls, a pretty ambitious project, and this is sponsored by Berkeley. It's a very interesting site. It's a site, really, for any field of study, no matter what your interest is or your proclivity or your hobby. There's anything on-line that you can possibly imagine.

Those of you that have been on the Web for a while already know that, but particularly now, if you remember back a year ago if you've been on-line...how many of you have been on-line on the Web for more than a year, going back at least a year? It was a little sparse finding things last year, wasn't it? You didn't have the sophisticated search engines you have now. Now you can find pretty well anything with a few keywords. The only thing you have is an embarrassment of riches, which is why we feel we exist with our newsletter, and that is if you

type in “biology” you might get excited at first that you have 2,700 hits back. But if you’ve taken some time to try to visit 2,700 sites, you know that you just can’t do it.

So there’s really almost too much out there now and we need something, more of a filtering mechanism, and that’s why there are many companies and many projects where they are actually filtering the sites out, filtering many that are visited, like we do. We pre-visit them and pick out the ones that seem to have the most content, the most relevancy related to the topic, and we put those in our Web site. And there are many Web sites out there; we’ll see a few of them here.

You can visit foreign countries, explore remote sites and download information from servers in that country, or servers that are about that country. In this case we’re visiting a server in South Africa. And here we have an interactive map, these quick little maps, [but there’s] a lot of neat technology coming out that will make this actually look sort of primitive. You’ll be able to click on any section of South Africa, and when you click on it it takes you deeper into the site, and deeper into the site, and deeper into the site. And lo and behold, there’s some learning information you can use, as well as [the fact that] you can print out these maps at any time, and with color them in. You can print out these maps and use them as a reference in a report, or have the students do multimedia reports where they can actually create almost a subset of the Web Page. I find that a very popular activity in the K-12 environment.

Something else interesting that you’ll want to keep in mind when you’re visiting these sites is to take a look, usually at the bottom of the first page somewhere — usually on the first page, but certainly on the site somewhere — is the Webmaster’s signature. And sometimes it’s simply “Webmaster at Berkeley” or something. Or it might be a person’s name. Take some time and click on those, even print them out or save them. These are people who have intimate knowledge of the particular site that you’re visiting.

For example, at South Africa you can e-mail the person that’s taking care of this site at the university site in South Africa. What better place to get more detailed information than from someone who lives there and is really intimately familiar with the knowledge that they put on the database, on the Web site? So [don’t] overlook that as a way of getting some extra information from someone who’s really involved in it.

This is the “Zoom In On Europe Site,” I call it. It’s a Europe site that is part of the Buffalo University project.

Simply click on the map and that will take you to an array of servers within that country area, and again, deeper and deeper into site [to find] maps and videos, all the color maps.

My brother was visiting Austria, and we were disappointed a little bit that we couldn’t find something that actually [was a] bed and breakfast where he was going in Austria. So at the last minute I decided to e-mail the Webmaster, and I e-mailed and said, “I can’t find anything, do you know anything?” Well, lo and behold, it was not even, I don’t know, 25 or 30 hours later, I got an e-mail back of 14 different bed and breakfasts. Not from him, but from somebody that he knew that lived across the hall or worked in the university or something that had a friend who had a friend, and we got a list of information that you just couldn’t get, up-to-date information that you couldn’t get otherwise. That’s a personal anecdote, but there are lots of others that directly relate to K-12, and again, you can get them by going deeper into these sites and finding out the people that are responsible for the site.

People that aren’t too familiar with the Internet always ask me, “What’s the language of the Internet?” And they don’t mean TCP/IP. They’re talking about “Is it English?” Well, English predominantly is what’s being used on the Internet, and of course, being “USAcentric” here, 68% of the traffic on the Internet in the world emanates from the United States. So we have

68% of the traffic; add it together with other English or predominantly English-speaking countries and you're going to get, by and large, [that] mostly English is spoken here on the Net.

There are also limitations in character representations. So if you're trying to config on the Net, you're going to have to have different software or different viewers in some cases.

Most places will put English sites on the Net. This is an exception, and this might be exactly what you're looking for if you're looking for indigenous information. If you want to look at something in Spanish, you're going to be looking for Spanish sites in this case. If you want to read about [inaudible], you're going to have to read about it in Spanish, in Español. That's the way the site is set up.

There are a number of projects that are being initiated at universities where they are actually taking foreign language sites and running them through translation software and having students that are learning that language go through and clean up the translations, and then vice versa, taking English sites and translating them into Spanish and German and French. So that becomes an extension of using the Web site in and of itself.

[There are] lots of virtual tours on-line. Anyone, anywhere, at any time can take interactive tours and again, with this new technology that's coming out that that you'll see hitting [the market] after "Internet World" — much of it was just released here — we're going to see more and more interesting things you can do with your Web browser, especially when Netscape comes out full-fledged with the inherent bugs wiped out of it.

Grand Canyon National Park was one of the first ones put on-line, and there are probably about 60 or 70 pictures and pages in this site. What a great way to just take a peek at what's going on at Grand Canyon National Park.

My wife, who's someone, believe it or not, who's not too into the Internet — she doesn't really understand it, doesn't even like to hear about it — says, "Why don't I just write away and get a pamphlet?" Well, I guess you could write away and get a pamphlet about it, but it's not going to be up-to-date information, and you're not going to be able to e-mail and have a dialogue with the person that put the pamphlet together.

Also, another thing that we're working on is special needs on the Internet. It's a book we're going to have out in the springtime. And really, when you think about it from the point of view of children being mainstreamed, inclusion is really a hot thing right now. How do you make it relevant to everyone in the classroom, or everyone that you're dealing with, or people that are [physically or mentally challenged] that are just not going to get to go to the White House, or they're not going to get to go to the Grand Canyon, at least from the East Coast here? Well, the Internet is a great way to broaden their horizons and get a look-see, a peek, into a lot of things in a more vivid way — especially in an interactive way with this new software coming out — [rather] than looking at flat, printed matter or having you just tell them about it. I really am excited about the opportunities for special-needs computing and sort of spreading the Internet down into the areas where many of these children get overlooked too much.

We cannot only hit in the United States. We've got here the *New South Polar Times*. Now, this is an Australian site, that's where it's hosted at, and these scientists are actually at the South Pole. Every two weeks or so, they say about every two weeks, they e-mail in text that is put up on a server and you can actually read the newspaper generated by the scientists. Would you like more information? Would you like to ask them a particular question? You can e-mail the scientists, they ask for your input. I guess they have a lot of time on their hands down there and they really love to get e-mail. There are several K-12 projects that have been developed around this particular site, where the classes have organized their projects dealing with these scientists — extended projects going over six weeks or so, getting information, asking questions, and actually sharing information. This is a really interesting site.

Complete Works of William Shakespeare. What's pretty interesting about this is that the way [this site is] laid out, so you can actually do keyword searching on an entire work. So if you're looking for that phrase and you can't remember where it's from, if you're a student trying to take a shortcut, you can go in and actually keyword search right to the particular phrase that you're looking for.

I sold a number of books to skeptical teachers who said, "You probably don't have something I'm interested in. Do you have anything on Shakespeare?" And, of course, we turn to page 83 of one of our books and there's a Shakespeare site, and they say, "Oh, I didn't know that was on the Internet." Someone has taken a lot of time to organize this site. There's a lot of biographical information, discussions about "Did he write this or did he not write that?" as well as the full text of all the works. And there's thousands of others like this; Shakespeare's just the more recognizable one.

[There's] a really interesting one, a labor of love by one of the scientists at NASA who's put together what's called "The Nine Planets, Two Or More, Information, And You." I don't care what you teach, there's more information about planets here than you're ever going to want to know about. It's a very, very scientific site, and yet it's designed to be very interesting to even fourth graders. And it's used quite a bit in elementary education to go take a look at the planets. It's interactive; you click on the planets, there are some QuickTime videos in there so the planets move around in projected paths and orbital paths. This is a site that also has links to current information about the Hubble Space Telescope. When the Shoemaker-Levy comet hit, this was a site that had the latest views and the QuickTime videos, and also when they have storms and different things going on in outer space. I'm not really into astronomy, but there's so much neat stuff on here that I find myself not even being so interested, but helping my son do projects using this site. We spend probably 50 minutes or maybe an hour on this site in particular, just digging out all kinds of information.

And this is a way to get students involved, rather than telling them to turn to Chapter 9 of a textbook and read it and so on and so on, and write something up. Send them to a site like this, get them interactively involved, have them download some things and have them share the information and put on their own multimedia presentation about a planet, or about the Shoemaker-Levy comet or about something else that's on this site.

Not sure about something? What to get them more involved? Ask them to put three questions together and e-mail to the gentleman that runs this site, and usually within a few days he sends an answer back to you. And there are lots and lots of related links that he's put on this site to point you in the right direction.

Again, a great government initiative for information that was hard to get otherwise is full-text searching within 24 hours of it being in the Congress. It's now available on the Internet. We can actually click on any one of these and get a list of documents, and we can actually do keyword searching and look for keywords in any document that's before the 104th Congress. In this case we put in a phrase, not just keywords, but actually English language phrases. I type in "Internet," or "telecommunications and education." Boolean [search] operators present me with a list of documents that they thought accurately matched what I was looking for, and if I click on any of these it's going to give me the full text of this.

All this [finding of] current legislation happens totally free, and it happens within, really, about 45 seconds of searching. You can get back almost anything you're looking for if it's there. This is the same information that used to cost \$60 and \$80 an hour through a commercial search firm.

But it's not all heavy-duty on the Net system. There's lightweight stuff. This is Theodore Tugboat from Canada; it's a Canadian sort of cartoon series, and it has a lot of information on here that you wouldn't expect. It's not just visiting Sesame Street and seeing the characters, it's

going into the plots and the themes behind them. You can actually join a discussion list about the plot of Theodore Tugboat. It's really a learning experience; it's structured that way. And I would like to see if Sesame Street would do something like this. I know they're working on something that's more interactive.

Global Show-and-Tell. The show-and-tell that we've all come to know and love has now hit the Internet, and it's worldwide. So it's not just kids in your class bringing in a few things they could sneak out of the house before mom caught them. My son wanted to take the dog to school, but if all the teachers allowed that, you know what would happen. But on the Internet he could put a picture of his dog up and he could talk about the things that are favorites of his.

Global Show and Tell is actually a worldwide exhibition. Students are encouraged to create art to put up specifically for this project. It could be scanned photos, it could be digital photos, it could be something from home they can bring in and work on and scan in or take a picture of; but really, it's original art that they're looking to put up.

This is from a girl named Megan in Crestwood, Kentucky. She thought that this would be something she'd like to share with the world. What's really interesting is that some of the pages have a Mail To back to them, so that the students can collect comments from other students around the [world], comments on the artwork that they put up that they want to share. It's very empowering and really, to students, if you want to instill in them a sense of self-esteem or a sense of achievement that what they're doing is noticed by others, what a great [thing] to use the Internet for, to put up something they've created — and then for them to get e-mail back from someone across town or across the world that said, "I saw your presentation, I saw your art. I liked it, I have the same hobbies as you do," is something that really builds the sense of excitement and gets them interested in using this technology for education.

There's an interactive book that's put on-line that's called *Walking in Jerusalem*. It's really neat. And it's interactive in that you can choose the chapters you go to in and out of sequence. There are a number of books like this on-line. If you've ever had choose-your-own-adventure stories... Have you seen those, where you go through a chapter and then you can decide "does the person take the right door, or the left door, or does the plane crash or not?" Many of those are on the Internet, and they're really good for creative thinking.

What's happening all the time is that we get the students interested in this and they're learning about technology. And if you believe, as I do, that it's really a global information marketplace, that we have to create information learners, then it's really lifelong learning and not just what you memorize in class. You don't finish school and then go on to real life; it's constant learning, it's lifelong learning.

Then you're going to have to believe that it's important to teach them about technology, and also to get them using technology in such a comfortable way that we think of it as the telephone, think of it as a pencil and paper, that it's just natural to use this technology. It's not something you have to gear up and do for an hour, it's just a natural part of their learning experience.

And while you're teaching them to use simple things like visiting the dinosaur page or a storybook on-line, they're using this technology, and it's starting to get inculcated so that they really feel that it's just part of the normal work flow, part of the normal learning experience. Because when they graduate, when you turn them loose out of college, when you turn them loose out of high school, they're going to have to have these information skills. They're going to have to be comfortable with it.

They're also going to have to be called what Einstein called "curiosity workers." And I believe that you really have to teach someone to be curious. "Curiosity is more important than knowledge," is what Einstein said. Because really, when you hire someone, when we hire people

to work at our office, I'm more interested or as interested in knowing that they are curious about things, especially if it's the Internet, than whether they memorized a lot of things and have a lot of facts stored, because that's static information. I [want to] know they're curious, that they love going out on the Net.

The writers we have are just gonzo about the Net. They stay late for free because they love surfing around and looking for neat things and trying to uncover neat and new sites, because they know that that's what's really going to be aiding their learning, is to find the new things that are out there. I need someone that's curious, you need someone that's curious, we need to encourage them to be curiosity seekers, and the Internet is a great way to do that.

All About Dinosaurs. [This is] a pretty interesting site, a whole Internet catalog by O'Reilly that's something they put out free on the Net, with lots and lots of resources. A few years ago, in '90, when it became more acceptable commercially to put information on from commercial providers to actually do a little bit of business on the Internet — it started probably in early '92, as some of the [AUPs] started to dissipate — O'Reilly, along with many other publishers really wondered if you could actually successfully give things away on the Internet and still have a market for your books.

There were many, many discussions, particularly in '91, '92, early '93, that this was a big, big threat to publishers. "If we put something on the Internet no one will buy our books, so let's just put an ad on the Internet and make them buy our book." Well, O'Reilly and many others have proven that it actually works the opposite. If you put the whole book on-line it seems to drive sales of the printed book. It seems a little hard to explain, but that's really the dynamics of what's happening, and O'Reilly has done a great job of disseminating information on-line.

[Here's a site from the] National Institute of Health; lots of information here, lots of data here. They have taken the approach of really telling you a lot of what's going on in life inside this site by putting in on the front page, which I think is a better way of doing it. Many sites have 65 different sentences or little phrases that are a hotlink, and you're supposed to wind your way through that. This is a pretty nice design, where they actually tell you that they have grants and contracts and scientific resources. They sort of categorize it in a hierarchy. It's pretty nice. This is their grants and contracts. Everybody's looking for money these days, and I'm sure there's a pretty interesting hit count on this page.

The Russian and East European Studies Page. I think the first time I came across this would have been in early '92; the editor has escaped me for the moment, and I don't know if it's on our card or not. You can actually get information from the East and Russian Studies Institute the next morning at 5 o'clock, and it's a compilation and a digest, a synopsis and translation into English of many of the newspapers in Eastern Europe. And that can be delivered to you by e-mail. A lot of that is now ported to the Web, so you can actually get better information on the Internet than you can get in the *New York Times*, unless you have the *International Herald Tribune* at your door the next morning.

And it really gets me ticked off when I read about people who claim that they are actually bringing a real life perspective to the Internet, and saying it's too much hype and there's nothing of value there. I just want to drive to their house and knock on their door down and say, "Listen, I want an hour of your time and really tell you what it's all about." Because there's great information on-line and a lot of it's on the Web, and what's not on the Web will be on the Web within the next eight months.

[Here's] Virtual Tourist, and don't let it fake you out. It is a virtual tourist, but it has little to do with touring as a casual tourist. It's not a travel site per se, [although] it could be used for that. But it's a great site, and if you get a little bit creative it's a great site for cross-

curriculum learning. It's a great site to find out almost anything you want to find out by going to country-specific servers.

I was in a presentation in Washington and a gentleman who has a long line of credentials, he's credentialed from here to there, actually interrupted at the end and said he really doesn't think the Internet means anything to education and he thinks it's just like the video learning that they brought out in the late '60s. The next comment was, "How do you know it's not the next laser disc, and how do you know it's not the interactive CD that was supposed to be networked that belongs to our schools," and so on and so forth.

If you came to think that of the Internet — or if you're sort of waiting for someone to come to a presentation and tell you that the Internet is the be-all and end-all that's going to solve everything, save you lots of time, present answers automatically so it's some magic crystal ball — it's not going to happen. And if you go to some presentation or a search engine and [expect to] find everything on the Internet, it's not going to happen. So if you can deal with those two things, and if you've realized intrinsically, inherently, and right out front initially that, "I'm not going to find everything that's on the Internet, I'll always miss something," and that it's not the be-all and end-all, [then] it's simply another tool, but a really neat tool, probably a better multi-faceted tool, a Swiss Army knife of a tool, then you can deal with it effectively.

But I don't want to see any of you writing articles that there's nothing good on the Internet just because you couldn't find something that afternoon or your connection went down or something, and it happens sometimes. It happens to me, and I own an Internet service provider company, and I couldn't get my e-mail for a day last week.

Clicking through gets you closer and closer, sort of zooming in on these sites. Are any of you interested, or are any of you getting close to or involved in putting up a Web site yourselves where you're actually being involved in the design of it? Quite a few, great. Okay.

It's very interesting to go out on the Internet and see what others are doing. Sometimes I wonder if that's really giving a great view, though, because just because someone is doing it doesn't mean they're doing it right. One of the books we're working on is the *HTML Mail Construction Kit*, which has several chapters in it on how to design a Web site. And you'll see — I'll make a few comments parenthetically as we go along that I personally believe are good ways to organize Net sites — but take some time and go out there and see which ones seem to be intuitively designed. Don't put the sum total of all your knowledge on the Home Page. That's been sort of an Internet sin that a lot have committed over the last year, although there are more and more books out encouraging you to have responsible Internet design, Web design, and some hints and checks on doing that. And I think you'll see the general caliber of sites actually rising quite a bit.

Here's a site where it's a little difficult to read. Their idea was that they wanted to give you a lot of sites to click from. I think it would have been better if they would have divided the companies up a little bit more so you'd have more clarity, so you could see better. But if you know generally the area you're going into you can actually get more and more information, and go deeper and deeper into this site. Off to the side they list economic tourism, news, and science, and you click on those and it takes you to sort of another level of the menu.

Oh, this is a site I recognize, this is our site, Classroom Connect on the Net. This is our site that we give away, obviously for free. We have someone working on this site full time, and basically what we do is we take much of the information that's in our newsletter and put it on the Internet and give it away for free. And it actually does drive subscriptions, because most people like to have it in their hand, delivered to them. But if you'd like to find out what's going in K-12 education, you come to this site. If you'd like to find out about educational conferences, come to this site. If you'd like to find out what our products are, come to this site.

This site also has on it something we call Classroom Web, and Classroom Web is our offer to anyone in the world: if you have a K-12 class, and you'd like to mount your pages, we will mount your pages for free.

There's another group called School Pages, I think, and they charge \$90 a month or something like that. It's quite a bit of money compared to free. And we do it for free. So you simply e-mail us; our e-mail address is on the information you have, and we will mount it for free. Now, we don't give you 10MB, we give you a few pages. But many schools are starting their own, and this is a good way to mount it. And if you told us you had 8 to 10 pages, we'd probably do that for free, too.

We have links and searches; we have search engine pages. We've basically tried to make this a one-stop shop for anyone in K-12, and we're going to gradually move to higher-ed. We are just doing a deal with a major publisher that I probably shouldn't announce yet because it's not signed until Tuesday — but a major publisher, one of the largest in the world — and they're very heavy into higher education. So we'll be [adding] more high-ed components to our site as well.

This is another with "links and searching." We've done what many others have done, and that is to afford to be able to do this and give this away for free. We're selling — providing sponsorship opportunities, is another way we call it. We're basically selling links for other commercial companies.

We try to keep it, in our case — and if you're designing a Web site you'll want to do the same thing — keep it very closely aligned to what your subject matter is, to what your audience is interested in. You won't find Midas Muffler, you won't find something that's really in-your-face advertising. What you find is a nice sort of gentle button, and it has something to do with what you're looking at. In this case it's a software company. And it's not just a software company that says, "Hey, buy your software from us." It's a software that has an amazing Web site that's fully searchable in about six different categories. So if you'd like to search for software, if you'd like to buy software, are interested in what's out there, you can put in keywords by subject category, by grade level, by Mac or Windows, or by company vendor. And so there are six different levels of searching, and it searches something like 70,000 unit databases and it comes up and gives you your choices. And you can either buy on-line or just use it for information searching.

This is one of the Pages on our Class Web. This is from Denmark, and this is what they wanted to tell us about their school. They sent us an image of their school, and there are several other images in this database. I think we put three or four Pages out for them, including information about their school and their students, just a lot of things about their area.

I would like to see them, and like to encourage them if they're developing something that's about their school, that maybe when they send up their Web Page they would include a couple of links. Maybe there's something else in their town, or something that they feel is relevant to their area. So when I go to visit their school, [I can] jump off and take a look at the Denmark server or at something else about their community. We're trying, in a long-range way, to promote the sense of community that the Web site can generate.

So it's not just about "Here's our school, this is about our students, this is about our school, and about our team," but about "This is about our school and our community." How about putting more links in about your community, even putting in, maybe, a special e-mail box if you'd like to ask questions about the community, and make it a school project where the students would be in charge of answering the questions that people from around the world would send in to inquire about their community?

Because, in a larger sense, then we'd have a world community where people from Denmark are learning about our school in Lancaster, where the students from New Jersey are

seeing this Web site on our Page and then clicking and finding out oh, here's a Denmark university server or a Denmark server about Denmark or whatever. And they can e-mail to the people responsible for that site.

Did I skip one there on zoos? Well, if you do a keyword search for "zoo," you'll come up with that Page. It's a really interesting site. And again, with these new technologies that are being announced even as we speak, you'll have lots and lots of opportunities by springtime to be able to view video clips and sound files of animals on the Web.

Web Home Room, a very nice site. This is more for those of you that are in the teaching profession that are looking for peer information, even higher-ed. And it talks about some initiatives that BBN was doing — and I forget the gentleman's name that's running this, I have talked to him a couple of times — but he has actually a lot of information on there, like why you should use the Web in education. We get a lot of criticism on that. "Oh, it's just neat technology, I don't need the kids to go on-line and look at zoos. I have a CD-ROM about zoos, or I have an encyclopedia at home."

Well, [there's] value to the WorldWide Web in education, and there's a nice paper on that at this site. I want to promote you to go to that site. Go to the Web site and get ammunition for those that you face when you're looking for funding, or when you're meeting people who don't think it's that important. Or, if you'd like just to incorporate that into something you'd like to propound, the importance of using the Web in education is a lot more than just saying, "Oh, we need an [inaudible] activity to stay up."

This site isn't very beautiful, but it's a beautiful thing. It's run by [Gleason Sackman], and it's just the richest site on K-12 Internet account activity in the country, the richest site in our country, but it's about the worldwide Internet account activity. And you click on the States, of course, and it takes you to the information. It's just pure, raw information, unlike many of the sites that we "ooh" and "aah" over. That one's value is really the pure information guide.

If you've seen anything about the Net you've probably seen the White House, and of course you can go into the secret rooms of the White House that you can't normally see, and download pictures. What I thought was pretty interesting is that they did take the step, they did a very nice job on this from day one. So the first time you went to visit this site, except for the fact that the image map was off a little bit, and [they] fixed that, is that it was really full of great information. So if you go into a room and you see a picture on the wall, you can click on it and it gives you a larger image of the picture and the history behind it. It's very interesting to see some of the in depth information that goes on behind the scenes in the White House.

There is also some stuff that we as taxpayers need to spend money on, but I heard on national public radio that they actually spend eight hours tracking Sox the Cat to get the right meow out of Sox. And if you go to the Web Page, a couple of clicks deep, there is a picture of Sox the Cat, and sure enough, just so you use the bandwidths most efficiently, you can click on that and download a file of about 110K on Sox the Cat.

Something a little more learned; [here's the] Teaching with Technology grade site. This should be in your hand-out as well. Well, [inaudible] you never see of Marilyn, and it's a very interesting site. [There's] lots and lots of information and ammunition on this site, and about teaching with technology.

That's come more and more to mean "teaching with technology." I usually say, "Oh, do you mean the Internet?" because I'm not sure anymore, because there's such a blending with using technology in the classroom and computer-mediated communication as opposed to saying, "Well, what I really meant was WorldWide Web in the class." I'm finding that in conversations, and sometimes for the first 30 seconds I'm not sure that we're talking about the same thing. But it seems to be more and more that the Internet is becoming overwhelmingly what we're talking about when we're talking about technology. And I'm not sure it's a good

thing. I'm not sure it's true in every area, but certainly in states that are 100% wired now it certainly is overtaking other sources of technology.

As many of you know, the Gopher is totally integrative, as is WAIS, and as are all the tools now with the Web browsers, so it's no trouble getting Gopher resources. And if you're into that site we talked about, Teaching with Technology, they have a Gopher menu built into the Web browser site as well.

Again, not a pretty site, this one in particular, but this is a very, very rich and robust site, and it has lots and lots of information that will scoot you all over the world, taking you to rich information sites. I believe this is the one that's at CERN.

This is the *Yahoo* page that was up the day I captured it. They've changed it a number of times. If you've read anything about it you know it's tremendously successful. [It was] started by two students, and now it's really an honest-to-goodness, wholehearted, probably heading for public stock exchange, commercial site. And still it's for free, because it's being sponsored. *Yahoo* is one my favorite sites to use, but I hear [about] many others like *Lycos* and *Excite*, and *OpenText* and more and more search engines out there. And until I actually finish reading the manuscript that we put together on searching the Internet, I guess I won't be able to clearly explain all of them.

We're doing a book on searching the Internet, explaining each of the search engines, actually going through and doing the same keyword search using each engine and comparing how it returns different sites. So don't get stuck just on *Yahoo*, don't get stuck just on *Lycos*. If you're really, really looking for information, take that extra few minutes and do a quick search of some other search engines as well. But there are several powerful ones on the Internet.

One of the things that *Yahoo* started doing, which is pretty neat, they take neat things that are happening now or today's news. There was a hurricane coming on, and they had put a Hurricane Felix hot button up in the upper left-hand corner. What they had done that morning, sort of from an editorial point of view is, "Oh, Hurricane Felix, that's a pretty hot topic today." They did a search of anything to do with that, plus sites that they knew would have information about that, and created a little index of that on a "hot page." [They] actually put the hotlinks up on Hurricane Felix so that you wouldn't have to go and sort through what they had to go and sort through. So they're putting value-add on these sites, and I think we'll see more and more of that where value-add is being put on sites, even when they're actually search-engine sites and you wouldn't think that was a natural thing to do.

So [here's some things from] weather radar on Felix from when I put this together, and we can see what Felix is up to.

The *WebCrawler*. This changed a bit after it was sold to America Online. [With it you can] conduct searches for information scattered across the world.

[One category is] English Natural Language Queries. That's a pretty large box they give you, and I've tried it out. They've put over 25 words in there, and it pulls back actually pretty, pretty accurately what I was looking for. Some of them give you a little window, but if you keep on typing generally it keeps going on, and you can get about 20 words in there.

So that's sort of where we are as far as neat things on the Internet for WorldWide Web, for treasures on the Internet, as I call it. But as far as where we're going — and really it's about content, it's not about the technology — but I want you to encourage you to do whatever you can to get the technology, get those wires everywhere, get everybody on-line. But it's really not about the technology, [even though] we have to do that first. It's about the information. But you know what? It's really not about the information. It's about the way we handle information, the way we share information. All of us can become publishers. I asked for a raise of hands and there must have been 30, 40 people in here that are involved in putting up Web sites. We're all becoming publishers in our own sense.

I was talking to the people from GNN today [about] the new software that they just started releasing a few days ago. It actually allows everyone that's a GNN — I'm not selling GNN, by the way — but everyone that has a GNN account automatically gets 20MB of space. And your mail address is simply the GNN address, slash, and whatever your user name is on GNN, which is a lot like AOL names. Which means everybody is now a publisher.

Where do you get the publishing software? GNN has it built into their software. So if you just simply click, click and log-on, and you get those first few hours for a few dollars or whatever; in their case it's 30 days free. Everybody has Web Page creation software, everybody has Web server space, bingo, just like that, for \$15 a month. Figure it out. Last year we were charging \$150 to \$300 a month for Web service base, now it's down to \$15 and \$30 from commercial service providers. This is where it's heading, folks, and it's going to be that it's not just the information, it's sharing the information, that collaborative world community that you can be a part of and encourage others to be a part of.

And it's going to be, more and more, adopted faster and faster. The change and the rate of change is actually increasing faster and cheaper with video and sound, and there's lots more. [It's a] technology-transparent medium, and that [means] it's platform-transparent. It's really about "Can you get a whole, can you use a graphical browser? Does that mean AOL? Does it mean the newest Netscape? Does it mean Netshark or some of these other neat names that are out here? If you can get to a Web browser, you can get to this information in the same graphical way.

And the emphasis really is on sharing and communicating, collaborating, and global awareness. I refer to it as the iterative learning process. If you like a constructivistic approach, I'd like to put in that text and that framework and that context so that children can go out and find the information, bring it back, and construct their knowledge by getting some of this and some of that and so on. Different methodologies. Some like to surf, some like to go in and just use text-based search engines. You get that information, you pull it together, put it into a multimedia presentation, build your own Web Page — which the students should be encouraged to do as part of a unit in your classroom — and put that Page out on the Internet.

Ask for a response, make it interactive. Don't just say, "Here's our school," or "Here's our class project," or "Here's something we've studied, we've done a unit on volcanoes," but actually encourage feedback. That's when you really get the idea of how global this is, when you start getting messages back from around the world from others that did a search on volcanoes. When your Page came up and they e-mailed you back and either added information or thanked you for sharing your information with them, all of a sudden it clicks.

And even the fifth-graders, even the third-graders get it that we're now in a global community, that this is where the technology is and it's not going to be boring, and it's not trouble to do the assignments, and it's not trouble to glean information. It's not going through the *Encyclopedia Britannica*, which is, I don't know, 30 volumes, or a 1,000-page reference book. It's instantly accessible, almost like random access. And they can be part of providing that information stream.

The Internet is a transparent medium in this way, too. Up until a few years ago it was really CD-ROM, CD-ROM, CD-ROM. Well, it's not that CD-ROMs are going away; there are more and more of them than ever. We're even producing them. But it's just that a transparent medium may not be mailing CD-ROMs to everybody who's interested. The transparent medium could be the Internet. I think it is the Internet.

In fact, the Information Superhighway from my point of view has been, since the term began being bantered around, really the Internet. And it's not what we saw last year where a lot of billions of dollars were being bantered around that this company was going to buy Bell

Atlantic, and this company is going to... I didn't ever think it was really going to be that, and wrote some articles [about how] that wasn't going to happen.

It turned out not to happen, and that is because it wasn't about the telephone companies and the cable companies getting together and creating either another network or taking over the Internet. It wasn't about AT&T subsuming the Internet, taking over the Internet so we wouldn't have control over it. It's not going to happen. And the transport medium is going to be the Internet.

AT&T just announced that their interchange service is actually going to be — they actually call it more “Web-friendly.” It's actually putting the emphasis really back over on the Internet.

And you've seen that with the commercial services such as Prodigy and America Online that the Internet is the common denominator. And those of you in higher education that have been on, maybe going back even to [Bitnet], and have used the Internet for years, know that that's really the backbone of everything that's being transported.

So we're going to see large CD-ROM repositories being transported over the Internet. You'll maybe have a CD-ROM tower, maybe a seven-disc tower at your school or at your university or at your business, and you'll be using that as a sort of very, very large hard drive. [With it] you'll actually be able to buy content from different places. There are licensing issues involved, of course, but that's the way the medium will be, CD-ROM over the Internet.

There will be no limits on database files; you can daisy-chain these things together. There's no cost to deliver updates to thousands at the same time. The technology is that you buy a CD-ROM and they don't want to hear about you complaining at static information. What you do is you hit an update button and you might subscribe; you might subscribe to a service that they provide to update it, especially if it's a news-magazine-type CD-ROM where the archive of 600-and-some megabytes is on the CD-ROM, but the updating — whether it's updating URLs in that CD-ROM or whether it's updating news and information that's ancillary to that — just subscribe to an update service and it will save that on a small portion of your hard drive, but the engine and the program and the main repository data are still in the CD-ROM. That's what you'll see.

It's starting to happen a little bit now. We're actually toying with the idea of doing the same thing, of keeping CDs updated by having you click on our server and download a small [inaudible] that actually is played by the CD-ROM software on the CD-ROM. It's more of a client/server style, which, if you've taken a deep breath and read some of the client/server magazines, and worked your way through all that terminology, you find that client/server, which is true Internet style, is now being applied to almost every other way of transporting information and having access to information. And, of course, instant updates are available.

The future of the Internet? Emphasis on publishing. Obviously the tools are almost free. If they're not free, they're almost free. And I call \$99 basically — it's not free-free, but really, if you look at some of the software that's out here it's unbelievable the things that some of the companies have done: Adobe — and I don't want to pick out too many, I'm going to miss somebody — but Adobe and SoftQuad and a number of other companies have great publishing tools. Microsoft has one out now. And these are very inexpensive in light of the fact you can publish to the world, and you pay once for a development tool and you can learn it in an afternoon or an hour and be out there publishing. I call that almost free. But there are, generally on the Internet, free tools to use.

Students find, collect, and discover information. They build their knowledge and turn around and disseminate it. And that's the iterative process that's going to be really evident in all businesses in the next number of years. Certainly by the year 2000 it's that iterative process of you going for information, taking it, massaging it, publishing it and putting it back out again. Add

value to it and charge for it, or just add value to it by putting it together and disseminating it as a part of a creative learning process. It builds esteem in global awareness. I think it's very important for students — I'm particularly talking about K-12 though it could be in higher-ed.

And there's more and more and more and more Internet. There are waves of funding coming. I know it doesn't seem like it if you're looking. I believe you mentioned to me that you were shy \$50,000 for a matching grant, so it seems like you're sitting on a dry beach. But I'm telling you there are waves and waves of money coming from corporations and from government sources, and it's starting to trickle down. Corporations are being encouraged, not only by the Federal Government, but we do it in our publications, and in business seminars I attend they're encouraged to reach out towards education.

Everybody says, "Oh, well, of course, you probably want an Apple piece of software," because I guess Apples are in schools. And it doesn't occur to them ten years later, "Why is it that Apple is in the schools? Why is it that the software companies that aren't developing Macintosh software are missing half the market in education?" It's because Apple reached out to the schools early on; they made that commitment to do that.

Do we have many business people in here that are actually running commercial enterprises? A few of you. Why is it that businesses aren't reaching out more to education? Well, in the past, quite frankly, businesses have been shunned by education. You made a foray towards the educational field and you got turned off. The first thing you said is, "Well, you probably want to sell us something. What's it going to cost us? We have no money; we can't pay for it." And education has been looked at, I'm sorry to say, from the commercial aspect as "Education wants everything for free. Let's ignore the educational market." So there's a little bit of fault on both sides. I encourage you to close that gap. The Internet is a common ground where you can agree on operating and leasing the Internet area. You can operate in an area where companies are giving huge discounts, 90% and 99% discounts to educational Internet software.

And of course, as you know from Netscape, it's 100% discounted, it's free to education, and the server software is even free now if you're certified as educational and nonprofit. So many companies are reaching closer to that, and I think in the late 90s with the Internet it's becoming more of a sort of a safe haven for everybody to meet.

Curriculum integration, living textbooks — we're working on it. I know of many other companies, McGraw Hill and Scholastic, are working on it. Why is that you turn to a chapter on history and you can finish the chapter and see nothing about on-line services, where to get information on the Internet? Why is that? Because of a long cycle of textbook adoption, Internet has only just arrived, basically. It's the oldest new technology, I call it, with the newest old technology. And the information — it's not about the technology, it's about the information — and the information has just arrived [with] 58,000-and-climbing Web sites, compared to a little over 3,000 a year ago. The information is on the Internet. Why isn't it in textbooks? Simply because of the life cycle of the adoption and printing them.

I've spoken at large businesses conferences and I've been out to talk to some big publishers, working with their Web sites, consulting and so on. They are scared, up until the last six months or so or last year, they're scared of giving too much away. In a total reversal of that, we're now seeing them actively courting Web sites, tying it into the textbooks, printing in light- blue at the end of the chapter to set it apart, "If you're looking for more information on the Civil War, here are three or four Civil War sites." Or, "Come to the McGraw Hill Classroom server, and we'll keep the links up-to-date. You type in what book you're using and type in the curriculum unit you're working on and here are up-to-date sites that have to do exactly with that." And they're realizing that the more value-add that they put into the textbooks, the more textbooks they're going to sell.

The reform? Well, I don't know too much about all the academic discussions on school reform. I know there are a lot of different camps that have been involved in many discussions, and I have lots of teachers in the family and some professors, but really, I want to set the issue of reform aside and take a look at the Internet as being a great reform tool. It's a great tool for collaborating. It's a great tool for disseminating information. It's the tool you need to wrap your arms around and embrace and do what you have to do to raise that last \$50,000 to get that plug in the library.

I think you said that if I gave you a computer, you'd have no place to plug it in. Why do we entrust our children to teachers? We expect them to teach the sum total of all knowledge to our children but we don't trust them to have a phone in the classroom. It's ridiculous. We need to work toward pushing for that kind of, actually, "low-tech."

And really, an emphasis on school-to-work. School-to-work has been taken in the past to mean teaching a little typing or some home economic skills or some welding or something and sending them out into the workplace. That's not the workplace anymore. The workplace is information technology. You have to start in third grade getting them ready for school-to-work. School-to-work is teaching them about using that technology and, from my perspective, it's teaching them how to utilize the Internet. Not just log-on, but utilize it.

Thank you very much for your attention. Our time is about up.

INTERNET VILLAGE
USING THE INTERNET FOR EDUCATION: FOCUS ON DISTANCE LEARNING

MODERATOR

Laverna Saunders

Dean of the Library and Instructional & Learning Support, Salem State College

SPEAKER

Jill Ellsworth, Ph.D.

Senior Partner, Oak Ridge Research

Laverna Saunders: [Today's speaker, Jill Ellsworth, is a] Senior Partner with the Oak Ridge Research Group, and is a consultant regarding education and business on the Internet for *Fortune 500* companies. She is also a popular speaker in North America and Europe about business and education on the Internet.

A former university professor and dean, she holds her doctorate from Syracuse University. She is the author of *Education on the Internet*, published by Simms, the *Internet Business Book*, *Marketing on the Internet*, and the *Internet Business Kit*, published by Wiley & Sons. And she was an editor of the *Internet Unleashed, Second Edition*, from Simms. She is the author of the popular on-line resource, "Dr. E's Eclectic Compendium of Electronic Resources for Distance Adult Learning." She serves on the Survey Working Group IRTF of the Internet Society, and she's an active Internet participant. She can be reached e-mail at JE, and you may want to write this down.

Jill Ellsworth: It will be at the end of my thing if anybody wants to e-mail me.

Laverna Saunders: Okay.

Jill Ellsworth: It doesn't say [it] as easily as it might, although it's located here in Boston.

Laverna Saunders: Is your Web address there?

Jill Ellsworth: Yeah, I'll have that on there, too.

Laverna Saunders: Okay. She has to leave immediately after her presentation, so she'd appreciate it if you would send any questions by e-mail.

Jill Ellsworth: Or walk with me to my next one, whatever.

Laverna Saunders: Okay.

Jill Ellsworth: Thanks very much.

Laverna Saunders: You're welcome.

Jill Ellsworth: Most people call me Jill. It beats, "Hey, you," I find. On the Internet, people are a little less formal than they are in the classroom, which I think is probably a good thing.

I'm going to talk a bit about the Internet and education, a bit about distance education and how that's growing so much, and give you some information about computer-mediated communication on the Internet and how that's impacting education as well.

The thing I have up here is just a little quote about the Internet, that it's an amazing worldwide system. Now, don't you like the chunky style it came in? I like that, about how we can reach documents, people, and so forth. Millions of people communicating. I think the two strengths of the Internet for education are in communication and in information. I call it drinking from the fire hose, because it feels like that some days.

And then I also say that I think that it may have become the best opportunity for improving education that we've had in a long time. There are a lot of reasons why I say that. I think the biggest is that we have kids who are interested now in learning how to write well, and the reason they want to do that is so they can send e-mail to people, or so they can put up a Web Page, and I think that's not a bad thing.

We also have the energized learner. The person, the kid, the adult, anyone of us — I'm called Our Lady of Perpetual Surfing by my husband. I'm the one who raised their hand if you're on all day. There's just so much information, and there are so many ways to become an energized learner on the Internet, for folks of all ages, including kids. I've seen children of a variety of ages get very excited about what they're doing on the Internet.

Recently, from North Dakota a message came to me that said, "How would you like to correspond with my 28 third-graders via e-mail?" And I thought to myself, "Do I really want to do this? Am I ready for it?" But it turned out that it was a wonderful thing to do. What I got were messages of varying lengths, some of them as little as one sentence — but a pretty good sentence — to pages and pages asking me all sorts of questions. But almost invariably the kids said, "I wrote this myself. My teacher didn't write this for me." And I think that's very important to keep in mind about the Internet. I think it is really helping literacy, too.

Let's talk about how the Internet and learning work. It's no surprise to most of you that it's a two-way communication. It can be synchronous or asynchronous, and all that means is that we can either do it at once, or we can do it in series.

It has an interesting interpersonal distance. Many of you know from trading e-mail, or working on the ListServ, or on UseNet and so forth, that there is this interpersonal distance, this coolness of environment where you can't look at someone's eyes and say, "Oh, I know they were kidding, I know they were joking." Or, "I know they said that with a sense of irony," or, "They didn't really mean it that way." And this interpersonal distance and cool of the environment can be a bit of a block to good education and learning on the Internet. It doesn't need to be, because there's ways to take care of it.

It's also characterized by not being time-reliant. I used to love getting e-mail from my students at all hours of the evening and morning when I could deal with it. I really like that. It was really nice to spend my office hours actually talking to students instead of answering the phone, because the e-mail could help me with that task.

It's not space-reliant. We all don't have to be in a room like this, together, to do education on the Internet, and I think that's a pretty powerful thing. While being in a room together does lend a certain community — there is a networking that goes on, there's a personal touch that happens — not having to be here together can also be a good thing.

We talk about education and the Internet as leveling the playing field, and by that I mean that on the Internet, you are generally taken more for who you are, or who you say you are, which can create some problems. But we're not so blocked up by issues of gender, issues of race, issues of economic status and so forth; we tend to be able, in an education environment, to take each other better at face value for what you know.

That creates some challenges, particularly for higher education professors. I used to be one, and a lot of teachers in that situation, a lot of faculty, don't always enjoy being quite so accessible or quite so easily challenged or so much a co-learner as the Internet sometimes makes us be. It does not have to be that way, but it tends to be that way.

We tend to engage on a personal level in some ways that we don't, I think, in the classroom. One of the things that I noted as a professor was that there were — and you know who these guys are — learning styles that tell us that some people learn by sitting at the back of the room. See, they're back there now. I know who they are. And they're listening, they're paying attention, but they're not your active, involved student who's sitting in the first row nodding their head and so forth. And sometimes that's real hard, because you see these people back here and you're going, "Hello!" But on the Internet some of those people who have that learning style, or that interpersonal style which is a little bit more shy, suddenly through e-mail or through Internet Relay Chat open up. You can get to them. You can reach them in a certain way that you can't reach them in person. Different people are different, different learning styles are different, and the Internet meets certain learning styles better than others.

Another thing that happens on the Internet, which is really pretty interesting, are what I call "intentional learning communities." These can be ListServes — you know, lists, the discussion lists. These can be UseNet groups, although that tends less to be there. It can be a group of people who e-mail around a certain topic. But what it means is that some of us can get together as learners and talk together about the issues that are important to us in a way that we sometimes might not passing in the hall, or doing our official things. So these intentional learning communities take all sorts of forms. But they're a little bit different on the Internet.

Learning communities can come in formal things. In higher-ed we have them, in K-12 we have them, in adult and continuing education we have them, and even in corporate training. One of the most overlooked educational activities that we have going on tends to be the corporate training angle, because it's growing at a very high rate.

And then we have the informal one, which is, of course, the Internet itself. It can be a vehicle for it, or you can do your own research. You can get to that fire hose, you can use the discussion lists. or you can find what I call "personal mentors." "Mentor" may even be too strong a word. But I've come across — oh gosh, I've been on the Net a really long time, maybe twelve years. But there are people who I can write to and exchange information with as a colleague in a way that we just simply did not do before. We've collaborated on articles — that's a kind of formal thing. But informally I'm able to say, "Listen, I've got this class, and this part of it just isn't going good, I've got this problem. Can you talk to me about it?" And the development of what I call mentors or significant other people in the field — some of them are in the field, some of them are elsewhere — but those person-to-person contacts are one of the things that the Internet does best. It keeps us in touch.

In higher-ed it's no surprise that all the major players use the Internet for a whole variety of things. Faculty has been using the Internet for a really long time in higher-ed for support for teaching, human networking, scholarship and research grants, service and jobs. Job hunting is now very popular on the Internet thanks to the "Chronicle of Higher-Ed" and a few other activities. But we're beginning to even teach courses using the Internet. We're using it to send data, using it to interact with C-U-SeeMe and other activities. That's coming a bit hard in many respects for faculty in higher-ed.

Faculty in higher-ed tend to be fairly conservative about teaching methods. Not completely, that's not a blanket statement. Since I was a faculty member, I can say that. But I found considerable resistance to using the Internet as a teaching vehicle when I was professor. My analysis of that wasn't that they didn't think it was a good idea; it's that they didn't feel that they had the skills to make it work. And none of us, not one person in this room, wants to seem stupid to their colleagues, or especially to their students. So I think it was more a case of being comfortable, of learning the skills that are needed — because there are skills that are needed — rather than a genuine resistance to it. There is some genuine resistance, but it isn't all that way.

Human networking, research and scholarship have been around a long time on the Net for people in higher-ed. [There's] lots of collaborative research, lots of collaborative writing and so forth. But the Internet recently has facilitated that a great deal more than it used to. Grant information you can find, service, jobs, and so forth. Those are traditional things for faculty.

Administrators are using it to put out all sorts of information, particularly now. There is a growing number on the Web, although higher-ed is not as "Webby" as, say, K-12, in a certain sense. Higher-ed is still a bit "Gopher-ish," but it's coming along, it's growing. Professors are putting up class schedules, syllabi, registration information, scholarship and financial aid information; [information for] alumni and parents, [and they're using it for] development, PR, all those good things including all kinds of announcements, calendars, and local area information.

One real, real heavy user of the Internet in education and administration is the folks in development and fundraising. They're real interested in reaching more and more people, and are finding that alumni and other development officers are using the Internet. So it's become a bit more popular that it used to be.

Students, of course, have their organizations. They have their career planning and placement stuff, projects and course work and research. Probably one of the most popular activities is job hunting and putting your resume on-line, on a Web Page, and all sorts of stuff like that. Organizations are using it — it's very popular. Students are beginning to use it for research, for papers, for assignments and so forth.

And one of things that a lot of people are finding is that — how do I say this nicely? Students are ripping off the Internet, and using it in student papers sometimes. And I've heard a number of complaints about that from professors. And I said, "Well, you know, it's really no different than library research. If you send a student to the library to tell you all the history of Franklin Delano Roosevelt, they can find that and give it back to you and regurgitate in the form that it came. If you will couch your questions having to do with, for example, what might FDR have thought about the Exon Amendment, then you've got a student engaged in some research and some thinking." It's just a case of how you approach it. But it has become a bit of a problem, and in K-12 as well.

In K-12, again, no surprises here. There's lots of access to information for kids and teachers, lots of collaboration among teachers and students, lots of access to software and programs and some delivery of instruction, more so in, say, Canada and Australia than in the U.S., although out West in the U.S. there is some delivery of instruction. They used to use ham radios; they used to use interactive TV and so forth, and now they're using the Internet a bit more.

And kids are publishing information. You go to Web sites for a K-12 school and you're likely to see things written by students for students, in an amazing array.

I'm from Texas, now, though I've been from Michigan and I've been from Vermont and other places. In Texas there are a number of elementary schools along the Colorado River that are collaborating — middle schools, mostly — that are collaborating on some real, actual research. That's what the students call it. They said, "No, no. This is real, actual research, this is not just stuff." The Lower Colorado River Authority handed out water-testing kits for certain pollutants and are having the kids do the testing and put their information on a Web Page, and learn how to analyze that data. They're actually applying those math skills, all those kinds of things. And the teachers are very excited about it because, as the kids say, "This is actual, real stuff." And they're proud of that. They liked the fact that it wasn't just make-work, but that someone's making use of the actual research that they've done. And these are middle school kids. And I think that the Internet has helped foster some of those relationships, especially among those rural schools. There are some that are at quite a distance.

Teachers, of course, are having a great time with professional relationships. There might be, in a given school, one math teacher of a certain kind, and he or she wants to talk to other math teachers, and has found that the Internet really helps that.

Access to information, of course, and research — those are all, again, the normal things. The human networking... I always, I always feel funny putting that up, “human networking.” As opposed to what kind? Well, as opposed to electronic. But bear with me, because I think electronic is also human.

There’s lots of curriculum development stuff out there, lots of methods, information, and lesson plans and so forth that teachers are able to trade with one another through the Internet.

This just reiterates a bit of the information about students and human networking, key pals, MUDs, access to software and access to information.

And so now we need to talk about access to the bad parts of town. The Internet, like any other large organization, thing — whatever we want to call it, organic being — has some stuff that kids ought not to have. The approach that I see successfully being used by schools is the creation of what are called “Acceptable Use Policies.”

Let’s say you have a third-grader. They’re about 8 or 9 years old. You would not take your 8 year-old, put them in your car, give them the car keys and say, “See you later.” You wouldn’t do that. You’d take them with you to look at the town, to go through the information, if you will. With the 10 year-old you might take them to specific destinations and ask them a little bit about where they’d like to go. By the time they’re 16, guess what? They want those car keys, and they want them for themselves. And the same developmental tasks exist for kids using the Internet.

Third-graders, 9 year-olds, need a lot more supervision about where are safe places to go. They need an adult there with them on the trip, making sure that they don’t get into the bad part of town. Ten or eleven year-olds you give a little more freedom to, but you still monitor what they’re up to. You give them destinations, use some of the tools available to you, like *NetNanny* and others, to change the access and so forth. That works pretty well up until 13-ish, 14-ish, because those kids are real smart about how to download another copy of *Netscape*. They’re not stupid. They know where to do this, they know how to do this. And they know where to find stuff.

I asked my husband about kids, and when he was kid what sort of material he got a hold of that maybe he shouldn’t have. And he said a paper boy and he would meet early in the morning at the fire hall before their manager came to give them the papers, and they would arrive plenty early. And do you know why they would arrive plenty early? There were *Playboy* magazines there to be had. His mom found out about it — he was 14 at the time — and she took that opportunity to say, “Here’s some appropriate behavior. You’re not going to do this anymore. Here’s how you’re going to do it.” She took it as an educational task.

And I think that when we think about appropriate materials for kids we need to think about level, we need to think about access, and we need to think about adult supervision. Kids, 10 year-old kids, it seems to me, should not be turned loose with a tool as powerful as a computer without checking on them from time to time about what they’re up to. Is your 12 year-old spending all day in his or her room, doing stuff you don’t know about? Well, I think we better look at it.

At school the schools have acceptable use policies that the parents and the children of a certain age sign together, and it talks about the logical consequences. I think that it’s impossible to imagine a system — well, there’s probably vendors in this room who would disagree with me — but I think it’s just about impossible to imagine that there’s a way to keep all children from materials that all adults agree are not okay. I mean, there’s a picture of Michelangelo’s

“David.” Well, it’s a naked man, but it’s art, so it’s probably age-appropriate for a certain group, but certainly not for others. So I think that it’s an education thing, and appropriate use policies need to be used. So, stepping off of my box...

The projects that are going on in higher-ed and in K-12 on the Internet can be usually categorized by a couple of different things. Maybe they’re person-to-person; that would be an individual to an individual, and that would be kind of a mentoring situation. A person-to-many is the way that the children interacted with me with their e-mail. Many-to-many, classroom-to-classroom, groups-to-groups, groups of students-to-groups of students, one person-to-many in a distribution. Computer-to-person — a little CAI, and so forth, using the computer as a tool. Computer-to-computer, and we set it running.

One of the interesting new things happening in education and on the Net in general is the degree to which the computer, the network, interacts with us as opposed to the other way around. We’re beginning to see search boxes and things like that where we can give it instructions, and it goes out to fetch and comes back and we interact: “Well, I really like this, but I really didn’t like that.” It’s getting very interesting. And you’re seeing projects of all kinds in education, at all levels.

Distance learning is, of course, one of the ways that education is using the Internet. It’s high-speed; even if you have a 2400-baud modem it’s still pretty high-speed compared with going to a place. The Net is not time-and space-reliant. It has the characteristics of both linear learning and nonlinear learning. By linear learning I mean first we learn this, then we read this, then we learn this, and then we read this, and so forth. We go it through it the way, in general, the professor or the teacher has organized the material. “I want you to do it this way,” and we go through it. As educators we’re very used to that.

With HTML and Web Pages, and all the interactive media going on both on and off the Internet, actually we’re beginning to have to deal with nonlinear learning. A person can jump in in the middle, a person can choose to skip something, a person can choose to ignore something or a person can choose to come in at the end and work their way forward. All sorts of things like that. It has great, great educational opportunities and liabilities both, because we like to think about knowledge organized linearly, and it’s pretty much of a problem for some folks.

When you talk about distance learning, you begin to talk about some of the needs that are present with distance learning that are present in other learning situations, but they’re present in different ways. When we interact over the Internet at great distance from one another, we have a lot of getting to know one another and forming a community is harder. We don’t see that face. We can’t sit and talk before class, or after class go out for coffee, or meet with one another informally and get to know each other. The Internet makes that a little bit harder.

One of the ways we’re approaching that is through trading pictures, GIFs and so forth. Trading URLs for personal Pages that tells all about your cat or your friend, and so forth. Again, fleshing out that person. But distance learning on the Internet has that problem.

Fostering the atmosphere of learning is also a challenge. In a classroom or a situation like this, we’ve set it up kind of formally. We know I’m talking to you. Lots of you are listening, and you’ll have questions later. But on the Internet we don’t have that atmosphere of learning, and you have to begin to foster it through maybe formal introductions, or ways of going around the virtual classroom together.

We also lack those contractual systems of a classroom. We don’t have the trappings and the formalities and so forth, so all of those things begin to be challenges when we talk about needs regarding distance learning on the Internet.

Here’s one of the other things that I find is a problem, no matter what level of education you’re doing. You get closure in a lot of different ways; sometimes closure for a class,

sometimes closure for a lesson. On the Internet, I have observed that it is the case that we have our formal class, but then we don't get the same kind of closure because people want to still e-mail with you. They've built that community, and there's a greater flow of not wanting to let go of those virtual friends. You see that in — I don't mean in real life, but off-line as well — you know, the party after class and so forth.

But e-mail really facilitates that hanging on together, which is not a bad thing. It's simply harder to get learning closure, that's all that is. And it's just something you pay attention to when you're designing distance learning things.

There's a lot of literature, a lot of stuff out there about computer-mediated communication. And that's what we do when we do the Internet. We have the computer, in a sense, assisting us in our communication and so forth. And the most powerful thing that seems to go on is this human-to-human [interaction]. I think that's one of the things the Internet is best at. The human-to-human can be, in distance learning, a bit exclusionary; that is to say, if we're doing a lot of back-channel e-mail instead of in our formal virtual classroom, people will have the feeling that something's going on they don't know about. Now, that can also happen with a regular classroom with office visits, but e-mail tends to be a great deal less formal than a meeting face-to-face between a professor, let's say, and a student. It tends to foster that person-to-person lack of formality that some people find difficult. But it's part of the human-to-human using this computer to facilitate the instruction. The person-to-person part is very rich, but it can be a little uncomfortable for some.

Then we have the huge area of information retrieval. And there are issues around this, particularly — it's always been true — some of the things I'll tell you about have always been true, but they're even more true on the Internet. Let's suppose you go to a site and you find lots of great information on — I'll use good old FDR again, Franklin Delano Roosevelt. Well, you look at the information and you say to yourself, "Well, gee, who wrote this? I don't know that person. Who are they? Do they know anything about Franklin Delano Roosevelt? How permanent is that information?"

Well, I can tell you, in a lot of cases it's not all that permanent. Could someone change the information? Sure, it happens all the time. So immediately you are in the driver's seat of trying to figure out what good information is. Where did it come from? It's history.

And on the Internet — lots of people are working on this — but you fill tons of information that you won't know the source of, you won't know the reliability of, you won't know who wrote it. And so it becomes of dubious value to you. Finding good information, valuable information, requires that we know who wrote it and know something about that person. What are their credentials? Maybe they're not formal credentials, because I'm not hung up on having — that the only way you know something is if you have a Ph.D. after your name, I can assure you. But we need to know that this person knew something about this, and that the facts are right, and so forth. It's a real issue, and it's not going away.

Also, I do my "Dr. E's Eclectic Compendium of Electronic Resources for Lifelong and Adult Learning," and on that I say, "copyrighted, it's mine." You can reprint it, you can hand it out to people. But you can't make any money off of it. I'm not, so you can't. But you can use it pretty much any way you want, as long as my copyright notice and my name appear with it.

Well, guess what, folks. I find it all over the Internet without my name on it. Somebody took it, and that's bad. I think to myself, "Well, you know, they're just ignorant or something, I don't know." I'm annoyed, but I don't really much get cranked about it. Occasionally I'll write a site owner and say, "Hey, here's the official version." But then you know what I find? I'll find it with someone else's name on it. I get a little ticked off about that one. Or worse — to me, even worse than that — I'll find it with errors introduced into it that I did not put there, but my name is still there.

Those are all issues about this whole thing of information maintenance and retrieval. How can we maintain the quality of our information and the whole thing going on about intellectual property? The minute you write or create something, it's copyrighted. It's yours. No one else may use it. You do not have to register it with the Copyright Office, although doing so offers you some additional protections if you choose to litigate. It's yours. Just because you found it on the Internet does not mean it is in the public domain, it does not mean that it does not belong to someone. So be very careful about that snuffing down of information without thinking about who's copyright it is.

Then we have the whole issue of computer-assisted instruction. And we're beginning to see some really fairly nifty on-line things; I found some very nifty tutorials, especially in some of the sciences and math areas. I think you're going to see more of that. Because what it means is, if I've created the educational materials once for my classroom, if I'll put it on-line, other people can use it, other professors, other teachers can use it, other students can have it. But again, it gets back to that quality of information. So it's something that's an issue we really need to think about.

Here's something I discovered in my travels teaching the use of the Internet. And that is that in fact, when we begin to teach using the Internet, there are several levels of learning. And I find that the levels of learning work as well with adults as it does with kids. We just adjust it a little bit.

The first level has to include all the information on why we are doing this thing. Why are we doing this? What's the context? What's the groundwork you have to lay? When I first started using the Internet to teach I was teaching oh, one of those very popular courses for graduates, the required Research and Statistics course. Talk about your popular person... although, usually by the end it was all right. But at the beginning we had a lot of this: "Yeah, show me." And I found that in that teaching, because I made them learn to use the Internet — and the word "made" is the key word, forced — the first couple times I did this, I didn't spend nearly enough time setting the context, letting them know why we were doing this so that they could understand what the tasks were to be accomplished. So level one learning says, "Why are we doing this? What's the context? What's the ground work? What are we up to here, guys?"

The second level is sheer mastery, sheer learning of the technology, the processes, the operations and so forth. I can assure you that folks who have not been on the Internet find signing on, getting their password, getting their user name, getting all that stuff together, much less learning how to use WinSock, if we're doing that, is very daunting. And unless we solve the problem of, "I can sit down at the computer. I am not going to break it. I can get on-line, and I feel comfortable about that," I can assure you that the rest of the learning doesn't happen. If I don't feel comfortable getting on-line, learning how to do that with the passwords or whatever it is, getting my mail, all those routine things — if you're a real regular Internet user as most of you are, it seems like a no-brainer. But it isn't; it isn't a no-brainer until you've accomplished the task.

Level three is then mastering the tools. "I'm proficient with it. It's easy." All that means is that we've made it easy. We've learned to do some searching, we've learned what the difference is between Telnet and FTP. We've learned that a GUI makes all that easy, and I don't have to worry about it anymore. Familiarity — it's like sitting down at a computer, turning it on and booting up *Word* for Windows or whatever platform you're currently using; it's a tool, that's all it is. It's easy. The Internet becomes a tool. It's easy.

Then we can really go into level four where we can use this application, and let's call the Internet for a moment an application in education to problem-solving. We can actually use it. We can meet challenges. We can solve problems. We can do our homework. We can engage

in chat. We can post our work so others may critique it. We may then download it and get it off of wherever we've got it so that we can do it.

One of the things that I decided early on to do that I felt the Internet really facilitated was when I asked my students to post research reports of articles. They were analyzing the articles for the kind of research method that was used and so forth, and I asked them to post that on-line. Then everybody else in our class could look at it, read it, download it if they wanted to, make critiques of it and get back to the person through e-mail. My students lived, in some cases, eight to ten hours from the university, so this worked well for them. They got their critique, but they had to learn how to get that off the Net and re-write and re-post and so forth.

This had two purposes. One is that I found that after the critiquing, the quality of the writing was quite a lot better, especially after they got used to the process. They didn't want to post things that weren't quite so good. They needed less critiquing towards the end of the semester. And they also developed skills using the Internet for research and so forth.

Level four is where we want people to be, but in all learning situations, unless we've gone through the rest of it, getting someone to actually use the Internet for problem solving, for searching and for meeting various business challenges or business case challenges, I found it didn't work very well at all. I tended to rush it. So after a semester of great frustration on their part and mine, we came to a meeting of the minds whereby I improved my methods. And each time that I've done it since then, I've learned a lot about how to help people do it. And I look back at my first semester and I go, "Well, that was terrific. How not to do things."

What I want to do is I want to work with this group a little bit, and my address and stuff is up there, but that's not what's important on this slide, it's just that I'm at the end of my slides for the moment.

How many of you are educators right now? How many of you use the Internet in any way? What is the worst problem you have with that? Anybody willing to stand up and let us talk about you and your Internet thing a little bit? You're willing? Good. Thanks.

M: [inaudible] not being able to save either e-mail, or network problems, server fees...

Jill Ellsworth: Ah.

M: Or my computer doesn't work or it's too slow.

Jill Ellsworth: Okay.

M: [inaudible]

Jill Ellsworth: Would you characterize those as technology problems or hardware, software problems? Or is that their way of telling you, "I'm having trouble?" I don't know. I'm just asking.

M: [inaudible]

Jill Ellsworth: Frustration?

M: Yes.

Jill Ellsworth: Anybody else have anything similar to that?

M: Over here.

Jill Ellsworth: Yes.

W: [inaudible]

Jill Ellsworth: All right.

W: [inaudible] the biggest problem on our campus.

Jill Ellsworth: Mm.

W: [inaudible]

Jill Ellsworth: Okay.

W: They're having a real problem, they're not [inaudible].

Jill Ellsworth: Right. I think that certainly echoes some of the problems that I've seen at my former institution. And it centered around two parts of this; one was access, and by that what they meant was dial-in so forth. And then, "It's too slow. It doesn't work the way that I thought it did."

There's a couple of ways that institutions are addressing some of this, I would say not perfectly.

Let's take this example here. One of the things that feels so frustrating in these situations is that there's a perception, and I don't think they're wrong, that no one's listening to their complaints. And many institutions have, because of this problem, instituted a formal process whereby we can find out what those problems are. When are they occurring? What is the access problem? And I'd very much encourage you to get students to help you document those things, because having been on the other end of technical problems in a former life, if you don't know they're going on, you can't fix them. That's true. But even when you know that there are problems, it's this diffuse problem thing that's not helpful.

One of the things that I really found that worked for some institutions is the creation of formal feedback to the "sysgods," whoever they are. I always call them the sysgods because that's who they are for me. Formal feedback. And this works as well in K-12 as anywhere else, to document all of that. Now, the problem then becomes — she's right. Certain times of the evening, those students cannot get in. What are alternatives?

And I'll tell you that the ones that I've suggested are not institutional solutions. They tend to be things like students getting together and getting an account on an ISP and forwarding their mail, being able to use a different system. It's not perfect. That's not a great solution. But sometimes it's the only thing that works. Some of my students got together and got a AOL account that they could work their e-mail from. Others got access from an ISP. Those are not the only solutions, but I find that where institutions are willing, let's try to help them.

Document what's going on, then they can at least take a stab at solving it.

What other problems do you notice when you're trying to use the Internet for education? What other kinds of things? Yes?

W: Well, actually I have, I work with [inaudible]. And I found that [inaudible]

Jill Ellsworth: Yes.

W: [inaudible]

Jill Ellsworth: No, they don't.

W: [inaudible]

Jill Ellsworth: Right. For those of you who can't hear, she's relating that faculty typically won't come to the training that's offered. They're hesitant about using it because they don't know what's going on. Anybody else have that one? Yeah. Look at all of these hands. Do you want to tell me a little bit?

W: [inaudible] very much the same way.

Jill Ellsworth: Yes, it does.

W: [inaudible] and a lot of isolated individuals. However, the upper management is a little older and more conventional and more reluctant, [inaudible] individuals trained and eventually momentum builds. Because the manager's got to find out what they're doing.

Jill Ellsworth: That's right. There's the need to know. I think that those are very common problems in education and in business, and I'll tell you what I observe. I observed exactly the same problem. The folks in charge of the computer center or wherever, IS people in business, whatever we want to call them, would arrange these terrific training sessions. "Next week at 2:00, be there, you're going to learn everything you ever wanted to know." And it went over like a lead balloon. As I observed this, one of the biggest reasons is that people, particularly faculty, don't want to go to that kind of session because they feel dumb. "Oh, everybody knows I don't know."

What I found works much better is a one-to-one, I'll call it a "mentoring" situation. You're assigned to someone who does know. I mean, I used to get these approaches of "Hey, buddy, you want to buy a watch?" out in the parking lot. People would say, "You know about the Internet, don't you? Would you tell me a couple of things?" It was easier one-on-one, you know, almost covert.

I do find that in those situations that managers or faculty — and there are some similarities between those two groups — react much better to knowing one person that they can talk to, that they can call, that they can network with, either informally or formally, because they feel safer in that situation.

Also a lot of faculty, a lot of educators, are self-propelled learners. They will learn a lot on their own, but they need to know some starting places and they need to know somebody who will answer that one question. I remember this, "Oh, cool, I got all signed on and I'm on-line, and there's this dollar sign prompt — now what do I do to get my mail?" I mean, it sounds so stupid, but I didn't know what to do. This was years ago. When I called the person they said, "Type mail." I went, "Okay." Then I did, and there I found it. But it was the one-on-one. I find that faculty, middle managers, CEOs, do not generally react well to group situations, because it's that self-revelation. "Oh, I'm revealing to you that I don't know. People are going to think I'm real stupid." And they really hate that. They really hate that. So that's just something I have found that works. And there's some research on that in the training research, the IT research, that supports that one-on-one approach.

What other things have you found that are troubling — or maybe nothing? Yes.

M: Maybe you could repeat the question after I finish this.

Jill Ellsworth: Okay.

M: I notice you use the word education.

Jill Ellsworth: Yeah.

M: And sometimes you use the word [inaudible].

Jill Ellsworth: Yeah.

M: Training perhaps. But I'd like to address the political question underlying some of this, that it seems that a bunch of people in the education business feel that computers are being imposed upon them as a way of saving money.

Jill Ellsworth: Yes.

M: And I'd like you to address the possibility of rebellions, like the...

Jill Ellsworth: Oh, like in Maine.

M: The college professors in Maine.

Jill Ellsworth: Yeah.

M: Who were forced to broadcast over the television...

Jill Ellsworth: Right.

M: [inaudible]

Jill Ellsworth: Right.

M: They resisted that.

Jill Ellsworth: Sure.

M: Technology can perhaps help them to save money, but when it becomes less of a tool for people to stage mail or to do this, their course plans and that sort of thing, it actually becomes some way of computerizing education, then [inaudible].

Jill Ellsworth: Okay. The question has to do with the ways — and I'm going to re-phrase it, because that's how I always do it. And I'm going to take higher-ed as a way of talking about this.

In higher-ed, in many institutions right now, faculty are under huge pressure for the public to know what in the heck it is that they do with their time, and to be more productive — ah, that famous "more productive." How can faculty be more productive? "Well, if we could

only get them to use the Internet and distance education, one professor can then teach five hundred or five thousand students instead of twenty. What a great idea.”

Now let’s talk about where faculty are right now. They’re under a lot of pressure. There are a lot of cut-backs. Part-time faculty are taking over full-time slots. We’re not replacing faculty. All those things are happening, and we are then trying to “foist” — that’s a word I’ll use — onto faculty technological fixes for becoming more productive. And one of the biggest ways is through distance learning.

There are many, many instances recently of faculty rebelling and saying, “No, I’m going to teach twenty students. I’m going to teach them in this room, and I’m going to teach them this way. That’s academic freedom, and I’m going to choose that. I am not going to teach five hundred students via TV or via the Internet.”

So the technology becomes the devil. The technology becomes the bad guy, the guy that we need to worry about, and becomes the focus of the issues instead of the issues becoming the issues. And I find this very, very common in higher-ed right now because faculty are being re-trenched, they’re being cut back, they’re being told to be more productive. And the answer — I used to be an administrator so I can walk the other side of the fence and said, “Yeah, let’s get those faculty to be more productive. What are they doing with their time, for God’s sakes? This is cost effective. Let’s use it.” Ooh, cost effective.

So I think in education, particularly higher-ed, we need to — but this is true in K-12 as well. As you know, some of the issues in K-12 have to do with class size and effectiveness, and class size as a measure of effectiveness; and where technology becomes the bad guy, the devil, is where I think it allows us to ignore the actual issues. The actual issues are, what are faculty doing with their time? Teaching nine hours a semester doesn’t sound like a lot to most people. What are you doing with the rest of your time? What are you doing with students? What is effective teaching, and so forth? And faculty are being forced into using technologies, and I think that’s another reason why we’re seeing some faculty saying, “No, I’m not going to that training, because if I learn how to do that, then I’ll have to do it.” I don’t think they’re wrong sometimes about that. I don’t think they’re wrong.

[Thank you for coming].

INTERNET VILLAGE USING GROUPWARE ON THE NET: TIPS, TRAPS AND TRAINING

MODERATOR

Laverna Saunders

Dean of the Library and Instructional & Learning Support, Salem State College

SPEAKER

Marsha Woodbury, Ph.D.

Associate Director of Education, Sloan Center for Asynchronous Learning Environments (SCALE), University of Illinois, Urbana-Champaign (UIUC)

Laverna Saunders: Welcome to happy hour in the Internet Village.

Our last speaker today is Dr. Marsha Woodbury, who is from the University of Illinois at Urbana-Champaign, where she is the Associate Director for Education at the Sloan Center for Asynchronous Learning Environments. The acronym is SCALE, S-C-A-L-E. She's also on the National Board of Computer Professionals for Social Responsibility. She graduated from Stanford — so long ago that she won't say when. Then she and her husband emigrated to New Zealand, where they have lived for 18 years. So we have a global expert here.

She has a Doctorate in Computer-Aided Instruction from the College of Education at the University of Illinois, at Urbana-Champaign, as well as a Master's degree in Journalism. She is the moderator of CPSR Global ListServ, a discussion about worldwide ramifications of the Net, which has over a thousand subscribers from all over the globe. If you want to communicate with Marsha after her presentation, her e-mail is — marsha-w@uiuc.edu.

Marsha Woodbury: Here, I'll put it up there.

Laverna Saunders: Okay. There. And her presentation today is "Using Groupware on the Net: Tips, Traps and Training." Thank you, Marsha.

Marsha Woodbury: I admire you very much for sticking around at this hour. I think that's wonderful that you are so good. You're good citizens of the Net if you stick around for the four o'clock presentation. I really appreciate seeing you.

I'd like to walk around down below but I can't handle all the technology that well, so I'll stay up here. I always believe in giving a little bit of an idea of what I'm going to talk about before I start, since some of you might have to leave early and you'll wonder what you missed.

I'm going to talk to you a little bit about our project, how it came to be and what we do. I'm going to give you quite a bit about what we're learning and a little bit, at the end, of talk about the future. So I apologize to those of you who are behind a pillar, as I was earlier today. If you want to move to a more comfortable place, please do; but I'm stuck here.

What I'm showing you now is a networking module, giving you a little bit of an idea of what we're going to talk about. We're going to talk about resources on the WorldWide Web and electronic conferencing.

Networking is the key of what we do. The information superhighway may be mostly hype today, but it is an understatement about tomorrow. We were just talking up here on the stage about it. Just a couple of years ago, if you went to a Mecklermedia's Internet World, you would have had no trouble getting in or registering or seeing the vendors; whereas today the people are lining up out on the sidewalks and you have to wait to register. The interest is just growing like crazy, and it certainly is with education.

The project that I'm on is called SCALE, which stands for the Sloan Center for Asynchronous Learning Networks — except that last thing we changed to “environments” because it would have been SCALN. We didn't like the sound of that, so we changed it to SCALE.

SCALE came from a grant from the Alfred Sloan Foundation, so if you're looking for some soft money, here's the place to do so. You can e-mail me and I can give you this URL. They are funding different experiments with Asynchronous Learning Networks. They're funding three different categories of projects. The first is using asynchronous learning; that is, I'm at one place sending a message, [which] you read at a different time. Not at the same time — asynchronous. This is used effectively on or near a campus.

The second project, the second category is for those within commuting distance of the campus. And then the third is very far or distant-ed. The main thrust of what we're doing this year is in the yellow circle [on the projection screen], the “on or near campus.”

SCALE began with a grant from the Alfred Sloan Foundation in October of 1993. That was just for an experimental class, and the idea was to investigate the value of these learning networks. The goals of these grants — and particularly in our case — were to provide a test of the value of these courses on a campus, not away from the campus but on a campus. Then, if we found some successful techniques we were going to disseminate our approach to other universities.

Also, we were going to measure three things. We were going to measure retention — that is, how many students dropped the class after a certain amount of time. One of our problems was in the time [it takes to get a] degree, we want students to move through as quickly as possible. When they drop a class, they lose time. So we are measuring how many drop the class.

And as the previous speaker [Jill Ellsworth] said, we are very much interested in efficient use of faculty time. This is a Sloan idea; it's not particularly my idea. But they wanted to see if they could make faculty time be used economically.

Then we wanted to measure the quality of student learning. Now, how do you measure that? That's a pretty tough one. But what we did in the initial stages was measure the classes that used asynchronous learning against the classes that hadn't on the same [basis] — tests and courses. Lo and behold, the students that used these technologies did better. [This is from the] preliminary results from the other Sloan grants all over the country; from Stanford to New York, all over, we're finding success in this realm.

Now, whether or not this is efficiently using professors' time is another story; it may actually be taking more time than they ever spent before. [I see] nodding in the front row. But we are finding some good results with learning. And I think the reason is, and maybe we need to talk about this, is that it's a very active learning.

So the key trend now with technology in education is moving from the classroom to access anytime, anywhere. That is the asynchronous learning model. We are moving away from the lecture presentation — the sage on the stage — to interactivity and active learning, where you are more of a participant in the process.

I like to think of the teacher as not the sage on the stage but the guide on the side — you know, helping the students in their learning but not being the font of all knowledge. We're moving from paper resources to digital, and we're putting our syllabuses on-line. We're putting our readings on-line, and we're getting away from paper.

As someone said the other day, that's one less excuse the student can use for missing a class. They can't say, “Oh, I lost my syllabus,” because you can say the syllabus is on-line. Also,

with asynchronous learning there is a little bit more of a chance for self-paced learning, for taking as long as you want and repeating exercises over and over again till you get them right. That is the old computer-aided construction model, but we're using that, as I'll show you later.

So our project, the SCALE project, is using four kinds of asynchronous learning. We are using specialized, stand-alone software. One of the products that we use is called *Circuit Tutor*. That is a strictly the most basic kind of learning you've ever done. It's routine; you get a question, you put an answer to it, and then if it's wrong a little message comes back that says "you're wrong," and you can ask for help. It's totally you and the computer. This is not on the network, this is just you in a room with a computer. Stand-alone software.

We're using conferencing, and I've promised to define what groupware is — it is a conferencing software where the students and the class can all talk to one another. We are putting course materials on the Web.

The last thing that we are doing, and probably the most exciting in the long term, is that we are doing these — I may have this wrong — CGI, computer-generated interface, where we are having the students write in their answers to the computer at a distance. You know, instead of the stand-alone software where you write in a practice answer, you actually write it into the Web and then get an answer back from a remote server on the Web.

This is very exciting because now we can get out of that model with just one person with the software alone in a room. We can move this out and make it accessible to hundreds and hundreds of students. So this is a pretty exciting development.

So what are we using? Well, we're using servers and Mac and PC clients and modems, and we're having a lot of students hooking in at night from their apartments and homes. As far as software, we're using groupware tools. Now, the ones that you may most likely have heard of is *Lotus Notes*, but we're not really using that in this project; we're using one called *First Class*, which I'll show you in a minute. And *Pacer Forum*.

Groupware are products that allow people to collaborate; they are one step beyond ListSrvs. Everybody sees what everyone else writes, up to a point — although you can divide off into groups where no one else can go in except for the people in that group. And it's pretty exciting stuff. We use Web browsers; we use *Netscape* and *Mosaic*. We use the stand-alone software like *Circuit Tutor* and we use things like *Acrobat* to distill documents so that they can be read both on Macintosh and on PC computers.

We are serving the residence halls on campus, and if we have to coordinate all these people we have to get them all to agree. It's not always easy; one of the problems we have at the University of Illinois is that we have about 37,000 students now and we have a lot of very independent-minded people. So getting people to agree on what the students see when they walk into the lab is something that we can't dictate from the top.

Somebody may not choose to call the communications software "communications," they might want to call it something else. We've been — for some reason, they settled on "Network Services," so all over campus if you want to use communications software you find it in Network Services.

So we have to, as I say, try to get everyone to work together. Students are using their apartments and homes, and our professors are using their offices. They're working from home or they are working from distant locations, and they can check in to their classes if they are in London or Paris or back on campus.

Our goal is to use groupware appropriately. Simply throwing technology at a problem usually doesn't work and will probably make a big mess; and I kind of agree with that. So we

are trying to find the right use for this product. Just to repeat myself, the asynchronous conferencing allows the student to decide when they want to work.

At our campus, and maybe at yours, we have a lot of students who have to hold down jobs, so they are going to maybe even two jobs to get through school. They log in at midnight, they log in at 9:00 in the morning, 3:00 in the morning — they choose when they are going to participate. We are trying to build a sense of community in large classes; at the University of Illinois we have a lot of large classes. A class of 500 students would not be that strange. We try to break it up and divide into small communities within that class, so that the students don't feel so isolated.

The students are reporting that they feel that they have more access now to TAs and faculty than they did before; but then we get back to the earlier question of whether the faculty has less time. At the SCALE project we have around 3,000 students on-line in just this first semester, and during the fall of 1995 we have had 40 classes in seven different colleges that are on-line. So we have a pretty big project going.

First Class is a software that looks like this — and I do not know if Soft Arc is out there showing this today — but this is the vendor that has made *First Class* available. It's used by business, and that is maybe a problem, maybe not, we can look at that later. It's built very much on an e-mail model, and each of the little envelopes down there with a line is an e-mail message. Above the horizontal line are conference areas. Just to read those out for you, one of them is about basic concepts and one is on resistance circuits. So this teacher has decided to divide the class up by chapters.

Pacer Forum, on the other hand, is a lot more colorful. If it takes a student 15 minutes to learn how to use *First Class*, it takes them practically no time to learn *Pacer*. It's very easy to learn, it's very colorful and inviting. It has one major drawback, and that is it's a Mac client, and they don't have a PC client right now. So although we all have found some advantages with *Pacer*, very few of our faculty are really using it because of that limitation, because access is a big problem.

But as you can see, there's a lot more of a graphical use in *Pacer*. You can use this software to send out course updates, and it will be read by the whole class. For the first exam, maybe the room has been changed — you can send colorful messages in any color and font you choose. This message is in blue, but it just as easily could be in red or magenta. It's a lot of fun.

We have what we call "virtual assistance" — that is, we check in very often to see what the students write in. This student is using *Pacer Forum* and has written in a message including a picture and sound. Of course, it's really my boss who wrote the letter, but he signed himself in as "Chris Student." And he says, "Hi, everybody, I can't figure out how to solve problem 3.5. I'm attaching a picture with a circuit and three equations I wrote. Also a sound file."

So then the TA looks at the picture and says, "Well, I can see what's wrong with that," and the TA circles what's wrong and sends the picture back. Now, in the old days, if you're working on your homework on a Friday night, you wouldn't get back to your teacher until Monday, Tuesday or Wednesday of the next week. But we check in often, and that includes weekends. We can give the students feedback right away, so it's a very timely way of learning. It's very efficient.

In *First Class* you don't even have to have a little embedded picture, you can actually send the picture so it can read right there with the text. So it's even more user-friendly.

We have a simulation that's going on that's kind of fun. At the Vet College the teacher puts his students on-line in groups of five, and they have a simulation: they have a disease breaking out on a farm and the students have to track down what that disease is. They have to order tests, they have to ask questions. "Has the herd been moved lately? How has the weather been? What have they been eating?" Those sorts of questions.

They have to do the whole exercise on-line, and every question that they ask and every test they ask for is logged by the professor so he can compare one group to the next. This got so fascinating for local vets that they joined in, too. It's now kind of a fun hobby. Everybody tries to participate in the disease breakout, whatever it is. They can actually measure how much it costs for them to track down the disease, how long it took them to get to it and get back.

I asked him, "Well, how do you have these groups use the computer?" And he said, "Well, they might have one person at the keyboard and they are all standing around doing group think together, and they have to use the computer even though they are all students on the campus."

Just to give you an idea of what it's like — this is an administrator's nightmare, but this is what I see. These are all the classes, just on one of our servers. We have two main servers just for First Class this fall, so you can see that I could never in a million years keep up with all the conversations in all these classes. But these are everything from Comparative Lit to Agriculture 100, Economics, Chemistry, Urban Planning, Sociology... It's been used all across campus.

My job — and that's why the talk was titled [as such] — had the title of training, but I was hired to help train people and I have to train faculty, teaching assistants and students. As you can imagine, I have three very different populations to train. The faculty have the problems of that we were discussing earlier — reluctance to expose their ignorance and so forth.

I have found that one-on-one does work best. I visit their offices quite frequently and try to get them set up there, and they are very enthusiastic and very creative; I couldn't even think of half the things they do for what to do with students. With the teaching assistants, some are very motivated, some just call it a job; they log in and do it and leave. So we have a varying degree of enthusiasm.

The students also have mixed ideas because they were not informed about this before they signed up for some of the classes. They thought they were just taking another section of Comparative Literature and found out they had to do asynchronous learning as part of the course; so some of them were a little shocked.

We approach it through workshops. For faculty we hold seminars for the campus and lunch discussions. I do the office visits. I do a million demonstrations. Then we do tutorials — I see a misspelling — created for access on the Web. The tutorials are like a *First Class* manual that's out there on the Web, and I'll show you a picture of it in a minute.

I am learning, after my first semester, that hands-on training for the students would have been very much better than any of the demonstrations I did. I mean, I might feel very important if I'm doing a demonstration and showing everybody how the software works, but in terms of everyone else learning it's not very efficient. People do learn better when they are actually doing it. It takes a little longer, and you have to hunt down the labs to use and get everybody signed on and it is a little labor-intensive, but it is a much better way.

We still need very good paper documentation, and we didn't really put full attention to that as much as we should. We had all this on-line documentation, on-line manuals on *Netscape* to see if we could access [those], but the students really do like to carry around that piece of paper, and we could have given that more attention. Here's what our *First Class* manual on the Web [looks like]. And that's all well and good, but, as I say, paper would also have been important.

Now, about evaluation. From the beginning of our project we've had a team of three people evaluating it right from the start, and when you have 3,000 students and 40-some-odd classes, that's a pretty big project. So the Office of Instructional Resources has been handling

that. They are using direct observation, surveys, interviews; they are having comparative data between classes that didn't use it and did use it as far as the student learning results go.

It was really interesting in one course — it was a classics course — where the students were given a questionnaire and it said, "How do you feel about using this networking?" And they wrote words I can't even say to you — "What the blank is this all about?" You know, it's very funny. I think that they got over their initial hesitation, but it was funny.

So what have we learned? Well, we learned that there is such a thing as the on-line teacher, and that it's a little different than the classroom teacher. You are in a different environment; you aren't getting the verbal clues from the student. You have to think about this — this is not something that you just leap into. You have a role. You have to help the student, and you have to help them become a different kind of student. You have to help them take a strong role in their own learning if they're used to having everything come from you.

The good on-line teacher promotes student-to-student communication. It's not a top-down process so much, it's — if you remember taking statistics and how you broke up into study groups and helped your friends get through, it's that kind of teaching.

The good on-line teacher likes to be available to students, because you are available to students. And if you don't particularly like that part of teaching, then this maybe isn't the place for you to be. The good on-line teacher gives timely feedback and gets on the Net fairly often so the students can start to count on that. You facilitate the self-pacing of the students, and you work harder to help students learn more.

I guess at this point you have to learn what an "emoticon" is. Those are the happy faces on the Net, if you aren't familiar with them; if you turn sideways you can see there's a frowny face and a smiley face. After each of your communications with the students, because we lack the verbal cues, we have to learn how to handle the emoticon so that we can express [something like] "I am joking here, I am happy here." Everyone tells me I'm the only one that does a left-handed happy face, but so be it. You have to learn that, too.

As I said, you have to develop this network persona. Now, in my case, do I want to be Doctor Marsha, Doctor Woodbury? Do I want to be Marsha? I mean, I want them to address me in a certain way, and I have to decide that fairly early on and set the tone with my students. When I talk to the TAs I'm very, very hard on them about this, because some of them are actually younger than the students they're teaching. We use undergraduate TAs in this project and they might even be 18 or 19 and be teaching somebody 25 or 30, so for them to establish authority it might be good to have their full name. I also tell them they can't date their students, which they don't like very much. But I don't recommend that.

The motivation for your students is going to come from you and you're going to transmit that on-line, so you really have to be keen on this. There's no point in starting if you really are reluctant yourself. That's where motivating faculty is really important, because they really should want to be there; the students will know quite quickly whether they do want to be there or not, so we urge them to be as warm and timely as they can be. It's hard to see, but we have little smiley faces on some of the little discussion groups just to have areas where the students can get in a chat.

One of the things that you can really do to help your students is get very structured, because the on-line world can be a very confusing place if all the communication is going in a big jumble and people are just sending message after message and it's all going into a big pile. So you start well before the start of the term and you set out clear discussion topics; otherwise you'll have a mess on your hands and a mess is hard on your students.

We did have a teacher who divided his areas not at all. He left it totally open and he got hundreds of messages in one long stream, so that everybody was writing and it could be — one

message could be, "What do I do on problem 5?" The next message could be, "I wonder if the Cubs are playing in Chicago this weekend?" No one wants to read though a lot of drivel.

By structuring your class you guide their learning and it also helps you structure your course. It actually is a very beneficial thing. So you must schedule and organize your course very thoroughly, and put the readings and assignments in place for your students. So, as I say, start early and get this going.

As we talked about in the last lecture, opening and closing discussion areas is kind of an important thing for the on-line students. They sort of — things keep trailing on. When you've finished one problem set and you've moved on to the next, you've got to let them know that that area is now finished.

Now, work groups. I don't have all that many suggestions to you, but maybe I will next year, on how to do work groups successfully on-line; we are having our teething problems with this. They do provide challenges. If you say to five students, "I want you to work on this project," some of them will say, "We like to get together in person, we don't want to work on-line." And there's really no reason why they shouldn't get together in person; they are on a campus and they can meet. But we often get students who have to drive 20 miles to the campus and it is very inconvenient for them to come back 20 miles to meet with the group.

We have the older, returning student. We have people who are working and we're trying to encourage them to get on-line and do their talking in their work group on-line, and some of them are very reluctant to do this. So I can't give you the answers here.

I think that the best model I've seen is the Veterinary Pathology I, where they did the simulation and had a time limit and they all worked together for several days. It wasn't an unending, long procedure, because I think for three days you can motivate students to get there and get together and get on-line, whereas over a long period of time I don't think it works that well.

I think another thing that you can do to help your students if you're going to have conferencing is to start it out right, because this is not the Internet, this is a classroom. A lot of students who are used to the wild and woolly Internet think they can pretty much post anything or flame anybody or do anything they like. So I kind of set the tone that this is a classroom. You can even have a policy statement, if that does any good or not. This one says, "Don't write anything in *First Class* that you would not say if you were to stand on a table in the middle of the lab and speak it." That's what one teacher put just to remind them.

We did see some evidence last summer of some flaming, not too bad. It was actually misunderstood. It was a work group, and people were kidding one another, but we didn't know they were in the same work group and we were kind of concerned about it.

Traps. I think one of the things — because this software is so easy to use, you can actually invade privacy very easily. One of the things that I do or I insist that we all do — I don't know that it's followed, but it's my policy — I think the students have a right to know who's monitoring the class. I think you need to tell them that other faculty members might be looking in and watching and see what's going on in that class.

On *First Class* each student can have a resume and tell a little bit about themselves, but I don't think you should make a student put his or her picture up on the Net. If for whatever reasons they don't want their picture up there, they shouldn't be forced to have it; it's like forcing a student to have a Home Page with a picture on it. Some people have concerns about their privacy, or they are not all that crazy about their appearance. One of the great things about the Net is that when you are talking to somebody in text, you don't know if they're fat or thin or if they are quadriplegic or if they're black or white or yellow or green. If we ask people to put their pictures up, then we're kind of destroying their anonymity and we're

starting to judge them by their appearance. So I would ask you not to. Just respect the students' right to remain anonymous if they wish to.

Also, as a teacher, on this issue of flaming and whatever, I think you really have to get in there and take a responsibility. You have to monitor it often. You have to separate for the students the areas where they can chat and talk about the baseball games and whatever and separate that from where students are asking questions about class, because they don't want to waste their time, if they're time is limited, reading a lot of drivel. So by separating out the areas, you actually help them. Again, [in terms of] flaming or abuse, you want to save them from any kind of insult.

If a student is really, really not getting it, you can withhold that student's privilege to write into the group. You can allow them to read, but you can actually make it so that they can't write. That's an extreme measure that I haven't seen taken, but that is something you could do.

We have had a problem with [the fact that] we use labs and students sign into the computers and labs. What could happen here is that the student could come, sign in, do the business they had to do, get up and leave and still be signed into the computer. The next student comes in and realizes that — here's a free ride, [with] someone else's name — and could start posting very insulting or even pornographic comments.

We had the pornographic ones happen last year in a group, and what happened was that the person who discovered this discovered it at 7:00 in the morning and erased all the messages that she had power to erase, but she wasn't able to erase them all. There was a high school group that had a discussion and, unfortunately, some of the students read some of this stuff. But it was just because a student walked away in a lab leaving himself logged in.

Now, one of the things that could happen to you as a teacher is that the students could want to talk to you a lot. And they could actually task you — I mean, they could really have you do a lot of work. They might like it on-line, they might like to send you lots of messages. You have to draw a line on that, too. A good teacher questions and builds thinking skills, so what you want to do is if they ask you to answer a question you really may want to hold back. You may want to just give some other students time to jump in and try and answer it first.

What you're really trying to promote is students talking to students and learning together. Maybe you want to ask those questions that lead to thinking, and that's kind of hard for some people who like to know all the answers. But maybe [it's not a good idea] to jump in with the answer straight away; throw the question back on the student so they don't get too dependent on you.

Since this is the Internet World, I want to show you a little bit about what we're doing on the Web. We have our own Home Page and we're using *Mathematica* software from remote computers in the way I was describing before. In other words, we're using the Web to access *Mathematica*, ask questions to that software, and have it spew back the answers. Chemistry courses are taking it.

Here's one where they're showing a problem, and the student has to write the answer in and will get an answer back from the computer. Is the answer right or wrong?

We're very proud at the University of Illinois to have *CyberProf*, which is another one of these wonderful things that comes out of our school. This is the same sort of thing, where very technical problems are answered by students remotely, and then they're given a hint if they get it slightly wrong and they're actually directed to the page of the class notes that the problem was in. And those notes are on-line.

Here's a multiple-choice test that's on-line for students. They can take this as many times as they like and get feedback on whether they are right or wrong. Then they can write in to the professor and say, "I keep getting this question wrong; I don't understand why it's

wrong.” And then the professor can say, “Well, you know, here it is, or here it is in the lecture notes.” So here’s a multiple-choice test, and this is what their answers looked like. They might get two right and two wrong or something like that.

[I want to address] the future. Well, what we would really like is we wouldn’t really like to teach two different kinds of software to our students. I’m saying this as the person who’s the trainer, but I would like to just teach one thing. I’d like to have it all be done on the Web, and I’d like to have the conferencing and the course materials and the drill and everything in one place, so that as a trainer I only have to familiarize the students with one kind of software.

We like *First Class* and we like *Pacer Forum*, the fact that you can send in your graphs for correction, you can send in pictures. Right now we haven’t found an easy way to do this, uploading the files to the Web and uploading pictures. We haven’t found a real easy way. We think we might do that through e-mail; we may have to do some kind of e-mail form to send a picture in and back. I haven’t had a full look through the exhibit room, and maybe there is already a Web conferencing tool that will handle everything. We haven’t found it yet, I can tell you.

We have to learn how to mainstream the technology and establish standards for using it. Mainly, we’ve got to make it easy. It’s still too hard. We have the problem of our modems getting overloaded in the evenings, and we have a lot of technical problems. So we’re a long way away. I keep asking for the Model T Ford of the Internet to come along, because we just need something to make it easy.

Then we have the problem, as discussed before, of motivating the traditional faculty. What we’ve done in our project is [make sure] they have the best access to the Internet of anybody. They have their own private modem bank, and we give them all the support you could want. We give them graphic design support, I go and train their classes for them, I train them. We also must see their teaching load, or they must see it as fair. And that’s something that is really hard in a university environment where we’re cutting back on money.

I guess my last parting thought for you is, when you’re through changing, you’re through. So that’s what we’re telling the faculty.

I’m open now to any questions, and thank you for coming to this late-hour talk on a dark and dingy afternoon. I really appreciate having you here.

What we have now — we are in the first wave and the first main semester — we have self-selected faculty. We have people who have volunteered to join this project, who have written us for computers and what have you; so we have people who are already interested in teaching, interesting in learning about changing. I haven’t had to work with somebody who isn’t interested in changing yet, so I can’t answer your questions as far as that. Most of them want the contact. I get lots of feedback from faculty that they’ve had better discussions with their students since using *First Class* than they ever had before. They are happy. But they are the self-motivated, self-starting ones, so I don’t know. Yes?

M: How do you adjust faculty [inaudible] project?

Marsha Woodbury: It’s all by department. We have no control over that; we’re sort of a service branch, so it’s up to each department how they are going handle it. We have some teachers who have three separate classes on-line, and they liked it so much they came back to us and said, “I want to put my other two on-line.” So I think they are teaching their full load plus doing it on-line, but they just love the interaction so much that they’ve wanted more. Maybe in some ways it makes it better for them. The reward is that they are getting more quality teaching.

M: [inaudible]

Marsha Woodbury: Yes, right now. Right now, uh-huh, that I know of. I mean, if some department is making some kind of a provision for this, then I don't know. Yes?

M: [inaudible]

Marsha Woodbury: <http://www.scale.uiuc.edu/scale/>, and then there's a /scale/. I should type it up for you. So it's www.scale.uiuc.edu/scale/. Well, I think that you've been a wonderful audience, and I'll let you go.

WORLDWIDE WEB MARKETING ON THE WWW: HOW TO PROMOTE YOUR PRODUCT IN THE MOST CLUTTERED ENVIRONMENT IN THE UNIVERSE

SPEAKER
Larry Chase
President, The Online Ad Agency

Larry Chase: Thank you very much for coming to "Marketing on the WorldWide Web." We are going to start our lecture about marketing on the WorldWide Web in this many-to-many universe with a childlike example. This is something that is actually on the Web site that we publish, so we get it in two different places; we show it here in presentations, and then people can see it on-line.

You get a document out of the same 10K small graphics file. This fellow is known as "froggie," and froggie in the WorldWide Web is a Net surfer. There are many kinds of frogs, and you have to figure out what kind of frog you want to talk to.

Some people ask me, "Well, how many people are on the Internet?" I have essentially two answers: one, I don't know, and two, I don't care, because if I am marketing to the Internet as a whole, I am doing something wrong.

I think it's probably a good time to say that, first, the Internet is not one market; it's tens of thousands and maybe hundreds of thousands of markets. Secondly, the Internet is not one medium. As an ad agency we have got a budget for TV, radio, direct response and the Internet. The Internet is really a tangle of mediums, and the WorldWide Web is just one of them under the Internet umbrella.

Today during the show we will talk a little about how these wrap together, and how you use the Web in conjunction with other on-line media like e-mail and UseNet. One is technical, one is graphic. Like in radio and television, one has pictures and the other doesn't.

Here we have a Net surfer. We have a depiction of your Web site. That's your Web site, a lily pad. If we go to the next frame, that's the WorldWide Web. So the problem that you are faced with, that everybody is faced with, is that the cost of distribution of information, commercial or otherwise, has plummeted through the floor. You don't have cost of distribution. You don't have cost of printing, cost of handling, cost of fulfillment, cost of postage, cost of warehousing in the case of catalogues. Although costs fall through the floor, it doesn't mean that it will replace any of the aforementioned media. It's augmentative, at least for the purposes of this demonstration.

This is the WorldWide Web, and you are a lily pad. By the end of the year there will be 5,000 other lily pads. The question then arises; why should somebody go to your lily pad as opposed to the Library of Congress's lily pad or the Met Museum's lily pad or the 800 Flower's lily pad?

What's the incentive for froggie to jump to the lily pad you have constructed for your frog or your niche of frogs, once you have identified your frogs? How do you get word out to those frogs that this lily pad holds some really delectable information or some novelty or financial incentive, which are the essential three core arguments that I see as being necessary to draw your kind of frog to your kind of lily pad?

How do you do that? You have got to send out messages that are narrow-cast to the universe of your frogs. So if we move on now, we will take a look at one of the pieces of "cyberbait," as I refer to it, that bring frogs to your site.

Let's go into content. There is a content war out there; you have a [continual spate] of magazines, as we know it in the physical world. We have got examples of content that's very indigenous to the Web. There are some sites that we visit every day. If we actually go into

something called NetDay, in there we see different things that are related to our business. Our business happens to be all Internet, all the time. We go to things that are "Internetcentric." There other cases and other industries in a business-to-business sense that will attract your market into your site.

If you take a site like Wiltel — a telecommunications company, I believe the fourth largest long-distance carrier — they mostly talk to telecommunication managers at large companies who buy in bulk, who buy a lot of bandwidth and telephone lines in bulk for the companies they work for. They have created a whole telecom index of things that are of interest to their community, their frogs, their target audience.

iWorld is something we visit, being indigenous to the world we work in. People who are in telecommunications are going to look at things that are indigenous to them.

Then, at some point, Wiltel would like our summary of information, the *Telecom Weekend Review* e-mailed here. What does this do for a company like Wiltel? It's very focused; there's no cost to fulfill it, and you build up a rather substantial e-mail list which is more of a direct response tool, an electronic-direct response tool, an e-mail list of qualified prospects.

Much in the same way, on a consumer level, a company like 800 Flowers will say, "Do you want us to remind you via e-mail," [which is] another medium of the Internet, and "would you like us to remind you that it's your anniversary two weeks ahead of time and send a dozen roses?" Would you like that? Only if you hit "yes," a year from now that happens.

In this high-tech, high-touch environment, the consumer will know that the things are robots and somebody didn't sit down and craft them a message; but they appreciate the fact that it's a good service. That helps me; that's a good reminder that I should be thinking now is the time to be thinking about buying flowers for an anniversary or birthday or what have you. It's not a bad idea; it's a relationship type of marketing, a longer-term relationship. That's what Don Pepper refers to as the "one-to-one future," and that is one-to-one marketing. To be perfectly honest, if the Internet didn't exist at all, marketers would still have to grapple with the one-to-one marketing shift that is taking place.

It used to be that there was not a lot of choice of information. Today I feel battered by information; by the end of the day I am sure you're overcome with information. You have got a brain full of it or a shopping bag or a pocket full of business cards, like I do, that you are going to have enter in. So you are going to need some filtering done and some choices made.

Of course, some of these things will happen in what they call "personal assistance," or "intellectual assistance," which goes out and looks for you. It gives a profile. I say I am interested in the following information: I am looking for a job six months out; I will be buying a car one month out, and I want two air bags. You will basically tell it where you are in your life, and it comes and brings in information, commercial information, a lot of it.

The point is, it will go out and automatically do some of the things you are now doing manually. Therefore, when programming your Web site in today's manual universe, you want to make sure that it attracts the person now, grabs that mindshare now and makes sure that the future habits that are basically being cast right now on the person who is surfing the Net. That's probably a good reason to get started sooner rather than later.

You want to make sure you're not just putting on sound bytes of your CEO. If you have got 500,000 lily pads and your basic message is, "come and download for five minutes [and get] a ten second sound byte of our CEO," that is not a very big draw.

Maybe it's obligatory that your CEO is on the WorldWide Web, but I don't need to see it on the Home Page. What I would want to see on the Home Page is something that excites me. I asked Glenn Davis, who does "Cool Site of the Day," what tickles his fancy. What makes a Cool Site of the Day? [His answer was,] "There is a little boy inside me. When it gets excited

about seeing a site, that's when I know I have something." You need to build and generate that excitement into a Web site.

Unfortunately, daily updates of sound bytes of your CEO, more often than not, aren't going to cut it. You will have to figure out what's in it for your audience to come visit. It's probably not a brochure. People may be willing to look for that, but not as a rule; they are much more self-centered. It's sort of, "enough about you, how about me? How can you serve me? If you want my attention, if you want my mindshare," as Don Pepper says, "how are you going to do that?" How are you going to get them to come back to your Web site?

What good is it if you bring somebody over to a Web site, and they hit your Home Page, and you're only able to show upper-level managers? We have two hits today, and we will never see them again. What have you accomplished?

Brand awareness advertising is important. It's an interactive medium. A lot of things that are happening today on the WorldWide Web are direct transfers from previous media that we have grown accustomed to over the past 50 to 100 years.

The same thing was true back in the 1940s and 1950s. Look at television in the States. You go back and look at the old early television, and you see Old Gold cigarette boxes dancing on stages for 60 seconds. What were they thinking of? This guy in the Oldsmobile singing opera to his girlfriend in a convertible on a set, and they act like they are driving. There is nothing going on behind them, but they are driving. There was no strategy; it was more like radio, or what radio people thought TV would look like, that's happening mostly on the Internet.

When I was a kid, I remember — I grew up in New York, and I remember we used to watch the test pattern on Channel 11. I used to call it, "the nothing on." Today that test pattern is burned into my psyche.

Howdy Doody would come on with the dog, with the wooden jaw and his dog Farfel. These were corny things. It's the age of Howdy Doody on the Internet. It's not going to take 30, 40, 50 years to go back and laugh; it's going to take three or four years because of the dramatic changes that are happening in technology as well as in bandwidth.

If you read the last *Internet World*, there was a very big piece in there, an interview with [George Gilbert]. That's another person I would encourage you to read; he put forth the proposition that the cost of bandwidth is going to fall as precipitously as the cost of computer chips. Gordon Moore's Law of High Tech says that the chip doubles in power every 18 months and halves in cost, so you have got a factor of four. He is saying that what happened to the computer chip in the eighties is going to happen with bandwidth from here out. I hope it comes true; I want to be swimming in bandwidth myself, so you will be able to have a lot of moving imagery.

Even right now there is enough to do without projecting very far out. What's after the Web? I have no idea. I am having a hard enough time keeping up with what's going on there. There is so much going on, we have got to — we have to catch on to what already has happened to realize that you can't just simply go around the WorldWide Web, go into an area, and then scroll to the bottom of the page and the advertisement. It has a name of a company. It's hyperlinked, and because it's hyperlinked you are going to click on it. I think the content and the advertising have to work side by side; it has to be an appropriate juxtaposition, otherwise it will be what I call the "we interrupt this content for an off-topic Home Page brought to you by the sponsor of this page."

If you had a choice of looking through an ad or continuing on with that story on page 36, would you read every advertisement? That is equivalent to clicking on an ad. You need an incentive, a content incentive, or financial incentive or novelty. You need an incentive to answer the critical question: "Why click here?" That's the question that you have to answer to get the

people over to your Web site. Why click on whatever you've set up and why come to your site? Click here to see my Home Page.

When we first went on-line, we had some slick graphics, some information about what we thought and what we have done for our early clients, but thousands of people went over it because they never saw an ad agency on-line. Today one goes on-line every hour or two. I saw another agency go on last week, and they had a focus group, an on-line focus group, and it says fill out this questionnaire this week. Come back two more times for two other questionnaires, and we will give you a T-shirt with our name on it. Let me tell you, if you come back to my site to fill out three different questionnaires over the course of three weeks, if you have spent that much time just for a T-shirt with my name on it, I don't think I want to know you.

You really do have to think of the surfers' best interest, because the worst thing they can do is ignore you. Ignorance is like, "I see you, but I am not paying any attention to you." Out of sight, out of mind is really where it's at on the Web.

You can build beautiful, fantastic, rich content on a Web site that's beautifully constructed, fast-loading and very well-navigated; but it's true you can build a Web server in the middle of a forest and nobody knows about you. You will find some hackers or worms that ultimately will find you, and you end up in some indexes, but ultimately you will need to build traffic into that site.

Your inventory is information or a financial incentive. You are a store. You have to put out the grand opening sign. You have to put ads in the local newspaper; that's what you do when you post it up to *Yahoo* or the *WebCrawler*.

What are you going to do for an encore? This is a problem that I see. A lot of people who call us have spent what they think is a lot of money building a Web site, good or bad, but they didn't think of the ramifications of updating. Whether you like it or not, when you get into the Web business you are now a publisher. When you put a Web site up, you'd better refresh it.

Barring the cost of entry and quality of content, when refreshing that content, costs gets higher and higher all the time. This is why I wonder whether a lot of subscription-based models will work. So if you are offering something for a subscription, a year from now you might have three other competitors offering it for free through advertising.

Maybe it isn't the 80/20 rule, where 80% of your revenue comes from advertising and 20% from subscription. I think more often it's the case that you get 100 percent of your revenue from advertising. If it's not advertising, then it's another method.

It might be comparable to comparing the costs to how much it would cost to put a salesperson out in the field. Let's say it costs \$200 to \$500 for a salesperson per sales call, no matter whether or not they are able to do anything with that sales call. I am talking more business-to-business; 800 Flowers doesn't have to send out salespeople. Maybe those are the figures that you should compare to if you are able to build a customer database from an e-mail list.

We have this information. We used to consider it proprietary information; here it's for free. You want to know when it's coming out? Tell us [you want to know]. Let's have your name, give us permission to talk to you and open up a relationship with you. That might be the way you have to rationalize your Web site if it's a business-to-business proposition.

The gas company — perhaps at some point there will be on-line payment with them. Have the customer enter it electronically.

You'll get your paycheck electronically; I have been doing it for five years. It's not a farfetched thought that I am going to be paying my phone bill on-line. Do you know how much money that saves them? If they are smart, what the phone company ultimately should do is say we will give you a five percent incentive; we will take five percent off your bill if you pay on-line,

because we are actually saving eight percent. That is more of a partnership with your customers.

Let's take an insurance company; there's a grudge purchase if ever I've seen one. Why in God's name go to an insurance company site? I don't hear any answers out there. Has anybody been to an insurance company site? I see a couple of you who must work in insurance. People buy insurance. What kind of decisions do they do around insurance? Well, they buy insurance because they don't know when they are going to die. Maybe if they knew when they were going to die, maybe they could have some handle on how much money to put aside if they could just manage to figure out when they were going to die.

So Northwestern Life Insurance Company was very kind to help you figure, give or take a few years, approximately when you are going to die. This is a great use of technology.

If I am doing estate planning, ITT Hartford has an estate planning calculator. It has a sense of humor. At the beginning, if you have an estate under \$1 million, it tells you don't bother. But it helps you figure where your assets should be. It will tell you, "Oh, you can't retire until you're eighty," according to how much money you have and the mortgage and the Volvo in the driveway. You need to know these things.

That's not a bad thing in a company like Northwestern Life or ITT Hartford Insurance. If you saw that technology there, you might go to their insurance broker. If you have to buy the stuff anyway, you might say, "Okay, send me some information or have a sales rep call me," or "I will call or send an e-mail." How much does it cost? Nothing.

To be perfectly frank, I will tell you how wrong I was when two years ago some journalist asked how long it would take for consumer companies to come on-line. I said I see that coming two and a half years away, and then two weeks later Pizza Hut came up and proved me wrong, pleasantly wrong. It's great fun to see consumer sites come onto the Web, and seeing the thing critically massing and going beyond expectations, beyond where I thought the thing would go.

While on the subject of consumer media, why should somebody make a purchase on the WorldWide Web as opposed to calling an 800 number? If there is financial incentive, a company like 800 Flowers, like a lot of companies on the Web, then pass some of the savings along to the consumers, and there is that incentive to do that. The consumer is empowering the provider of a product or a service to provide that product or service.

It's not too dissimilar to when Gateway opened up the sales channels of magazines. The thought of buying a computer from a magazine was preposterous; you go down and you want to sit at it, look at it. Now it's hard to find computer stores. I know more people who buy them mail order just so they don't have to pick the thing up and bring it to their house. They know computer commodity items and brand names, and people feel comfortable buying them remotely.

While on this consumer thing, when 800 numbers came out, people did not rush to their telephones to give their Visa numbers away to a stranger in Iowa. They weren't comfortable with that; their habits had to shift. Just because it can happen doesn't mean it will happen overnight. People have to come into it comfortably.

You will get "early adopters." Everyone in this room is an early adopter, or what we call "heat seekers." A heat seeker is someone who — normal people look at a problem and get a solution, heat seekers look at a solution and go and figure out what problem it solves, and how to use it as a competitive advantage. I suppose most people in this room are in the latter camp, because they are here. That's what the Internet is, it's a heat-seeking device, a competitive tool.

Federal Express allows you to do package tracking. This is perfect for the direct market. It turns out that UPS also has it, but Federal Express was first in that position, and got attention

and was seen as being a leader and innovator in the field of package delivery — in a medium that competes with their core product. But they were open-minded.

A gentleman by the name of Bob Hamilton carried the flag on this. You have got to follow through and use what is there, because if you don't somebody else will. You might as well do it earlier. You might as well write the agenda, rather than having your competitor write the agenda and then having to follow that script. Write the rules of the game first. We did it.

Let's go to WDFM. This is a personal history; this is the anatomy of the Internet business. This was originally internal information for our on-line ad agency. Eight or nine months ago we didn't let this information out, or if we did, you paid dearly for it. Then we got the idea that we'd sell it as a subscription, \$125 a year, and we launched a subscription service and got a lot of checks. At some point someone will offer that information for free. What will happen? I was greedy. I had these checks. I had to tear them up, and you have no idea how that pained me to tear all those checks up. Normally \$125, now free. But it built traffic, this content built traffic, the kind of traffic that a company like an on-line ad agency wants. This is self-defining traffic.

I don't know how many people make it here. I don't need to know. When they fill in the guest log and tell me what company they are from, that they are the executive vice president for a Fortune 1000 company, that tells me enough. That tells me where I am in the food chain of being a Web marketer. It's hard to find those people. Almost half the people that come to visit this site are people in the IS area — information services.

I find MIS [marketing information services] people are more apt to adopt marketing concepts than the other way around. You have to understand the topography; MIS people do better because they have been surfing the Net for a long time.

We didn't know who was visiting; this was before the tracking schools. In the guest log, we give you an incentive to fill it in. Everything has an incentive. The Web is more like a direct response and sales promotion, because it elicits a response. We know better than to ask you to give us information out of the kindness of your heart.

In the guest log we will tell you where we get our best information. If you want it unfiltered, fine, be our guest. That's how we got something like 1,500 people filling out the guest log, because we gave them a reason. As a consumer I am in the same situation. Do I fill out guest logs just because they ask me? Frankly, I don't have the time. I suspect that most of the people out there don't have the time either, the same way they don't have the time to come back and fill out a questionnaire three times for a T-shirt.

You really want to respect the user's time. You can make certain conclusions about who's out there: they are connected; they are on a computer, modem, and probably reasonably well-educated. However, even in these early days of data-gathering we don't know who is there or how many.

Again, I hearken back to the early fifties, to Procter & Gamble and Colgate and other major advertisers in TV media. TV sales are really skyrocketing, [they figured,] and a lot of television stations are going, so we'd better start buying products like the TV version of the soap operas and start producing those.

In the early days the advertisers owned content and the ad agencies managed that content for them. In a very real way that's happening again. You keep hearing that content is king; well, it happens to be true. That is what people look for out on the Net. Sometimes that is commercial content, sometimes it isn't, but you do have to work under the philosophy that some aspect of commercial content is actually sought after by customers.

Look at classified ads. One of the most successful revenue streams for a newspaper is the classifieds. They're for jobs, real estate, for travel. Classified is a searching kind of mode to

be in, and that makes the WorldWide Web a very nice place to have certain kinds of classified ad information. It could be classified ads, but the model is different.

Yahoo is essentially a classified ad medium. You have the model, we will list you for free. Just like the Yellow Pages where you get a business line; they give you a free listing, but if you want that listing in bold or a little more, you want to display it in red, [it costs] different tiers of money. The same thing with *Yahoo* and *InfoSeek*.

We go to *InfoSeek* and you put in the word "hotel." Somebody puts in the word "hotel" or the word "travel" or "weather" — which are fairly popular search words — and people go out there. Trends of search words are popular, so you put one of those words in your banner.

We will do search for hotel discounts. You have to assume someone who puts in the word "travel" or "hotel" might be interested in discounts on hotels. It's a safe assumption. So Hotel Discount happens to be one of our clients. We made this purchase, this media buy. We made this media buy for them, because you actually buy the words. We didn't want it to be so random it would just go into utter rotation and come up anyplace.

We should know that this service is out there for anybody who's looking for travel or anybody who's looking for hotel accommodations, which are other keywords that we bought.

You can do the same thing on *Yahoo*. Then you get that banner, and this is the equivalent of having a display ad in the Yellow Pages, where you are paying extra. You are probably listed down in the regular listings as well, but you want a premium position and you have to pay for it. It's advertiser-supported. It makes perfect sense.

By its very nature, it's financial incentive. I think you are going to see a lot of incentive kinds of companies. If we go to Airline Discount, this is a different kind of media buy. For Hotel Discount, we went to the appropriate groups in *Netscape* and in *Yahoo*, *What's New*, *Mosaic III*, *IV* and *V*. Hotel Discount is up and available on the Web at its URL. That's great.

Again, what do you do for an encore? Where else do you post? It stays up there for three days or less. Because there are thousands of sites going up a day, you need to weave yourself into the fabric of the Web. One of the ways that we did that is we went out and scanned around for "affinity" sites, and ironically enough Airline Discount went up the same week.

So, on our client's behalf, [we approached them.] "Hello, Airline Discount, we are representing Hotel Discount. Shouldn't we point to each other? Somebody looking for discount seats may look for a discount hotel." "Yes, excellent idea." We did that sort of affinity relationship, cross-linking with probably a dozen sites. These are deeply embedded.

Does that mean that we get thousands of hits off these sites every day? No, it doesn't mean that. Does it mean that we get fewer but more qualified hits, hits that are more apt to convert to either a sale in that session or in a session two, six or twelve months out? I firmly believe so.

Back to Hotel Discount. We found out something; we call it "just-in-time" marketing. When we launched Hotel Discount, we were staring at the Web, logging on in almost real-time. "How's it going?" "*Yahoo* just kicked in." "Wow, *What's New*. That's great."

It kind of trails off, and then just stays there. It was mentioned in the *New York Times*, *L.A. Times*, and it goes up and down like that. What we found was that we started getting some conversion.

So we found about 20% of the people coming into the site — [and we found this] just by looking at the Web logs — would give us the domain names like .NR and .DUS and ones that had European addresses on them. Well, okay, 20% of that's interesting. We figured maybe about 20% come from Europe. We also found that 20% accounted for 50% of the room nights booked. Wow, that's where the action is.

Then, of course, we quickly postulated, why is this? Let's figure it out. Maybe because the discount channels in Europe aren't as well entrenched — sort of a Wal-Mart on-line. So we have frogs coming over from Europe to visit our Web site; how do we get more of them to know about us? So we had to do — it's like a sales promotion, and event planning. Here is what we did.

We took a drink of water; then we thought about it. We said, okay, if you are a tourist coming over from Europe to the United States or going from one city to another, do you have to change your money? Out on the Web there are some currency converting programs. Bob Olson has a great currency converter. This is a great thing. Olson has one in Canada, and some of them update daily. Olson has one in Switzerland. We talked to them on behalf of Hotel Discount.

We want to mirror your calculator, [we told him]. We don't want to recreate it, we just would like to mirror it over on our Web site, and then run promotions to Europeans coming to the United States at certain sites they are apt to visit while traveling abroad, [where they can] check out our currency converter on the Hotel Discount site. So Olson said, "We will work out the deal. We will tell you about the currency converter." And [for us], that gives us a hook to go out and tell that target audience to come back to the Hotel Discount site.

While you are on the Hotel Discount site, there are other neat things. You might find a free subscription or three months' trial subscription to *PC Laptop*. You won't, but it's an interesting idea. It's an idea for perhaps people who are in business and traveling, and may have PC laptops. I know we are talking to one provider about supplying this to members of the Hotel Discount Fast Book Ticket Club. I can say, for members only maybe, that ThinkPad batteries are 40% off. Whatever it is, [it has to be] something that has an affinity, has a relationship to it.

I can't stress enough that it must be contiguous to the product and service, and therefore to the audience that you are trying to serve. There's a long-distance company [that has a] clickable map, a museum magazine. That's very nice, but I don't understand. I don't understand why a telephone company is talking to me about museums. If that phone company had that clickable map, and I click on the network and click on in Chicago and find how much I would save with their volume discount business-to-business plan, that would make more sense to me. I think a lot of these promotions don't make sense, and only serve to confuse the customer.

I worked at an ad agency that had quite a lovely reputation for many years, and Bill Burnbeck said, "if you are going to turn a man upside down on a page just to get somebody's attention, you had better be selling zippered pockets." Whatever the gizmo or the come-on, it has to flow naturally out of the product. Otherwise it can and will confuse the customer.

Oh, by the way, there was a typo in the catalogue in your program yesterday, on the publishing thing, and I apologize. It meant to say "Disseminate Information on the WorldWide Web," and it came out "Decimate Information on the WorldWide Web." So I'm sorry; I don't know how many people I lost by that in the seminar.

Anyway, that's the currency converting calculator. It's not too dissimilar to the "how long are you going to live calculator," the longevity calculator. There's also another one out there; it's not in our bookmarks today. It's called "Books that Work." This is a good one. Books that Work has an interesting calculator, a paint calculator. You tell it how big the walls are including the window space, whether you want to repaint or not, how many coats, and it comes up with how many gallons of paint. To me this is where the creativity is. This is what creativity is moving towards, how to take the technology that there is now and use it appropriately to deliver some kind of value.

There is enough technology today [even] if it didn't move any further, and of course it will. We've all seen very impressive things with HotJava and speed on machines and what have you, but there is enough going on today that you could have lots of good fun.

There is a Dutch auction site, very basic, very simple. Sometimes we can't get in, particularly at this time of day. I don't know why the lines sometimes jam up, which is unfortunate, and which is another reason why when we did that Olson calculator we only wanted them to give us a real-time currency feed for our purposes once a day. Olson is talking to a financial audience, and they want to market this out to financial companies like Merrill Lynch and so forth, and real-time is of more interest to someone like that.

Because of connectivity problems during the day between here and Europe, we decided once a day would be fine. It keeps the cost down, and for the traveling person who's just looking to change their money we think that would be fine. Just because the technology is there you don't have to use it all; that's what we learned from that one.

We are going to the Dutch auction. Still trying. This is all Dutch — does anybody in here know Dutch? Okay. It's a great site, just take my word for it. We are probably having connectivity problems. At the top of the page you have a picture, a picture of an Electrolux vacuum cleaner. It says that it's 900 guilders, and then, using that push-pull technology, 15 seconds later it says 850 guilders. 800 guilders... And suddenly it goes away and up comes a microwave, 900 guilders. It works. To me that's terribly creative; that's the kind of creativity that comes from mixing together an MIS person, an UNIX programmer, an art director and an account person. We call it Web therapy; the two of you have work together and cross-pollinate. You can learn marketing from these guys, [learn about] the content, the look and the feel.

Make sure you decentralize the operations, and [make sure] it has an editor, because everything points to each other. We noticed a site recently where there were 75 of their dealers independently up on the Web. You would think that the company would point to them, if for no other reason than because of a good relationship with the sales channel. Just say XYZ Motors Dealer Groups [on your site] — that was one of our suggestions to them, to point to them and relate to them. How much does hyperlink cost? Nothing. Help them out. Maybe even use what is called "cooperative advertising."

When local retailers run advertising, you will see a typical ad and at the bottom it lists 44 dealers, your local tri-state Honda dealers. I've rarely seen this concept on the Net. Diversify the cost centers, particularly if you have a system of franchise operators or a direct sales force. Bring them into the channels.

I saw something under nondisclosure that really handles this very well. It's very touchy; This whole idea of manufacture and service dealing directly on a one-to-one basis with the end-user is a very touchy thing with existing distribution channels.

Having said that, I have seen what I consider some brilliant executions of how to bring in those competing, badly bruised and abused distribution programs, co-opting them into the process and giving them the sale. It was masterful. I saw it as a major problem, because you are getting a lot of shifts, and a lot of middle people are going to be disintermediated. That is a 50-cent word [that means] you're cutting them out of the process, out-sourcing them.

This was something that I remember hearing Martin say to an ad agency. "Don't disintermediate. Don't farm out everything. If you farm out everything, you will ultimately farm out the value." Then the client will say, "what value are you bringing to this process?" You have to ask yourself how to stay ahead of that curve. From what I have seen, clients are really sharp on this stuff.

Again, since the research is very crude at this point, all I can tell you from my own personal interactions in working on the Web and gathering that guest line is that there are one

heck of a lot of senior people out there who are doing their own surfing. I am sure there's a lot of college interns doing it and printing pages and handing them up the ladder, but I can tell you that there are a lot of people who have a passion for this.

Let me go back to the creativity thing, back to the frog in the lily pad scenario. What was the frog in the lily pad scenario? Okay. People are often drawn in by just novelty. I mentioned, I don't know how long ago, the dancing Old Gold boxes. Why do people watch that? It was a novelty. People sat there stunned for 10 years watching that until they realized they could get a sandwich or something. It was a novelty at the time. Now there are a lot of novelties out on the Web.

There is a site, a graphic of a football game, and along the top of it is the Goodyear blimp. It asks you questions about football games, and if you get the answers right your team moves along the field. You have a couple of things to do. You can finish playing the game. If you play the game, you win a hat. You are there because you're a football fan, but they also have a baseball game. This is content, unusual content, creative use of content. I don't know if a copywriter thought of it or an ad person or MIS person thought of it; it doesn't matter. It draws something like 15,000 to 20,000 people a day. That's a neat place. That's one topic.

When you go to a football game you expect to see the Goodyear blimp. So you go to the blimp — or in this case the virtual blimp — and you click on it. Instead of taking you to the Goodyear Home Page, there's a sweepstakes behind it. What it says is that if you answer a few questions about tires you can possibly win a ride above the Super Bowl in the real Goodyear blimp. That, I think, is great marketing. The Goodyear site was up for a long while before that promotion came along. They had something there called "Tire U." or something. I don't know about you, but I don't get up every morning and think I have to know the latest about those steel-belted radials by Goodyear. But they make it interesting; you interact with it a little because you are here on their site, and you probably like football and would love to go to the Super Bowl. It would be the experience of a lifetime to go up in the blimp and see the Super Bowl from a "blimpy" perspective. The thing would just look like a big sandwich.

Okay, let's play. Do you know any football? Play a game with yourself. We are at the two-minute warning. Play a game, go to the sweepstakes. If I am interested in football — and I am not — if I had the possibility to see that game from the Goodyear blimp, I might go and take that challenge and learn a little more about tires, which may not hurt me. That would be great.

They do not interrupt this content for an off-topic; it is all part of this content, part of the topic. The payoff is on the topic because you get to ride in the blimp. That one was well thought out. That's where the creativity is. Who writes the headline? Who writes the copy? That's creative. Let's face it, that's been done before. Anyway, you get the idea.

We are going to [the site for] Mr. Potato Head. I hope there is enough bandwidth for Mr. Potato Head, which actually was renamed because of a trademark thing. I am not sure what I would do with this one yet. We want to give him a mustache and some eyeballs and things like that. The technology is here. Here's a creative challenge. What do you do with it? How do I use it in the way that is right? Right now it is a novelty. Should Lego use it? Maybe Mr. Potato Head himself should use it. I use it all the time; but again, I couldn't say, "come see Mr. Potato Head on the on-line agency." What do I get out of that? See people who are big Mr. Potato Heads? Why is he sponsoring that thing? It doesn't make any sense.

Let's go to Yahoo. There's a bunch of things, interesting things that are connected to the Internet. There's a whole list of these things. There's a guy out there who has this little camera that looks like an eyeball. His whole life is on the Internet. He is an engineering student out in the Midwest somewhere. Most of the time when I go to that site he is pointing down into his laptop, hammering out code.

Why couldn't you put a coffee pot on the Net and have Folger's sponsor it? Like give a pound of coffee away every hour, or have the "Folger's Morning News" and buy content from the *San Francisco Examiner* or *The Globe*. Play with it. Put it out there, have some fun with it.

Recently, in one of these seminars a few months back, somebody from Campbell's Soup said, "What does Campbell's Soup have for people to come and visit?" Maybe you want to put a thermometer for the top 25 cities, or maybe you want to put out different things like a cracker section — I don't know, I'm just winging it. Just to go and look at a soup can, I am not sure [that would work].

Have a mascot, have a dog that — they never know if you are a dog. It's perfect for Alpo or a dog food company to come in and have a dog. Have a mascot, a real dog that takes e-mail. It's probably happening, and we don't know about it.

One of the people who is doing a real interesting thing here is CNet. I happen to like CNet. CNet is [Studio Cam]; you have a half-hour hyperlink that runs on the Sci-Fi channel that points to the Web site every week. The Web site points to the television show, so you can find out in your market when it's going to air. It's perfect. This is tune-in advertising. If you listen to the radio, it sells you to watch television — "Watch Diane Sawyer on 60 Minutes on CBS, Sunday night."

If you watch television, it says "Listen to all news radio." If I look at TV Guide — god knows, there's lot of ads. There you are, in print, telling somebody to go watch television.

What we have noticed is that with the WorldWide Web and Web sites, CNet has found there the perfect synergy of promoting one channel to another. But there is a danger in driving direct analogies; direct analogies with previous media only go to a certain point, and then run the risk of being too literal.

You should think of your Web site as a cable channel in a limited site. It's programming, and you have to refresh it. People aren't going to watch Court TV replays. It has to be new stuff. You have to have new content. Hopefully, you have content in-house that you can refresh.

In this particular case, CNet is about the media on which it rides, and about new technology. It does a lot of stories about the WorldWide Web. You've got John Devoriak talking about different Web sites and technology and Web related things. TV is only a half hour long, but a Web site is infinite. Web sites are running a stream of URLs; URLs specifically find your operation or where to download that video or whatever it is. I think it's very well done.

If it were my money, which is the question I ask on behalf of my clients, would I spend it this way? How many qualified people are apt to hit here? If it were my money, I would want my advertising to come up at the top of the page. When somebody says this page received 200,000 hits — I won't even get involved in what a hit is, I will walk away from that. This page received 200,000 hits a day or a million hits a day. Maybe this page did get a million hits a day, but you can't tell me they scrolled all the way down to the bottom to get the advertisement. You don't have that information.

If I am advertising, I want my banner at the top, not at the bottom. When I walk around the Web I notice that most content tends to position advertising at the bottom. When you have a magazine, and you open the front page of the magazine, what is the first thing you see? An advertisement, what they call the "inside cover" or the "first cover." Then more advertisements, and then you see the table of contents. I think it's same thing with the Web.

In fact, some people actually like it because the advertising should tie-in. There should be a cross-merchandising effort. When I look at my Delta frequent flyer miles to check to make sure they caught the miles for this flight, when I get that thing that says, "here is your frequent flyer miles, you now have 200," what else am I going to see? I am going to see stuff from Hertz, stuff from 10 hotels; because if this guy is flying, he is probably going to stay at a hotel at the other end.

The same thing with a Web. It's more of a direct response, a sales promotion and event promotion type of medium than a branding vehicle.

That's my radical viewpoint. A lot of people would disagree with me, and that's good. There should be a lot of disagreement on what is what. In terms of what I would like, in terms of research, I would like to see somebody come up with where the conversion came to. A conversion can be many different things. A conversion for 800 Flowers can be a \$30 to \$50 sale; a conversion for Liberty Mutual or for Northwestern Life is somebody saying, "send me some information." That's a pretty good conversion. You have a customer who asked you for information. I call that a conversion.

The kind of information that I want out of research, as somebody who spends advertising money on behalf of clients, is the kind of information that tells me ultimately where that conversion came from. The person who converted it — where did they come from? Did they come from *Hot Wired*? Did they come from *What's New*? Did they come from *Yahoo*? It gets more complicated as you go.

It's something really radical if I find out that I get 50% of my audience from one particular hyperlink. Maybe instead of spending X amount of dollars on a hyperlink, maybe I give you a cut of the action, maybe I do a revenue-sharing thing.

There are analogies in my mind to radio. In radio this is called PI, "per inquiry." Sometimes late-night radio will make deals such as, "We will set up an 800 number for this commercial. We will run it and you pay 25 cents for each person that calls." That's not exactly a sold conversion, but at least it's a lead. Maybe it's on that PI kind of basis.

In a second I will tell you how I think the WorldWide Web is also like radio in terms of selling media. In sales there is a pattern I'm noticing; people have put tens of thousands into sites, many with good content, many with not such good content. [Then they'll realize] "My god, we are in the publishing business, and we don't have a sales force."

Originally they were going to go for a subscriber model; then they realized, no, free and open. We will sell to advertisers if we are content providers. We will feature advertising prominently because that's what the advertiser will want, and we will encourage the advertiser to do something that is specifically tuned into the content that we are talking about, so there is cross-sale. As in the case of insurance, maybe insurance should have a hyperlink to a car or automotive site. If you're buying a car, you're probably buying a new insurance policy for that car. That kind of tie-in is what's appropriate and what is called for.

[You need a] sales force. What you are seeing now are little companies popping up on the East Coast, on the West Coast and some in the middle. Many are going to advertisers directly, saying, "Can we buy a spot on your Web site?" I get a lot of phone calls, "Oh, you are an ad agency, do you want to sell advertising on my Web site?" [They do this] without realizing what an ad agency does. Keep redefining, keep being flexible.

Of course, a lot of people will come to our agency and say, "Okay, we have got a site and we want to launch it with advertising." That's great, but if I were an advertiser and it were my money, I'd ask, "Well, how many people do you have?"

"Well, almost one."

"Almost one."

"He's been spotting trains out in the desert for 20 years."

Okay. How many people do you have? You are asking \$10,000 a month to sponsor the site? Look at the quality of content. If there is nobody appreciating the content, what am I buying? How much per head?

Some people are saying there is a CPM model of \$20 per CPM. So people are saying if it's more consumers, it's more like \$5 "cost per thought." Some people are paying 10 cents a click. If it's just a drab banner and nobody clicks, you don't look too hot; then it becomes in my

interest to make sure that your product, that your service directly addresses my franchise and my audience, and is attractive and appealing to them.

We did a CNet studio. Let's go to the lemonade stand. There is a little girl at a lemonade stand. How much does it cost to put a Home Page up on the Internet? We get this question probably half a dozen times a day, from calls from all over the world. A little sign that says, "Lemonade 15 cents, Home Pages 10 cents." The idea here is that if you have an AOL account or a Prodigy account you can put a Home Page up on Internet. It's no big thing any more. Getting notoriety simply for putting a Home Page up is gone; the real question is how to put a marketing plan up on the Internet. Who are you aiming at? What do you want to tell them? How you are going to promote that on-line and off-line is something you want to consider very thoroughly.

I will go back and share some of the inside stuff on WDFM. Every nickel that we make on advertising we plunge back into the promotion to keep building the traffic to the site. We use that. Even when we make money, we use it. We make sure we don't make money; we want to keep getting more traffic in that will raise the rate card. That puts us in touch with a lot of qualified prospects.

You can imagine that people that go to that site are probably somewhere along the food chain. We may want to have a conversation with them. We are apt to e-mail back if they give us permission, and that serves us very well. We are not really looking at it for a profit center. The revenues from advertisements goes back into it.

We will pause here and take some questions.

M: Most of the people that are on the Web are educated engineers and technical people. What about the rest of the people that you want to reach, the bricklayers, the bus drivers?

Larry Chase: There is a supposition that most people on the Web are technical people. What about the bricklayers and bus drivers? It's a good question.

I don't know when the bricklayers and bus drivers en masse will be on the Web, but I think there are more than just technical people on the Web. It was my speculation two years ago that it would strictly be technical people on the Web, and I was quite wrong about that. There is a whole generation of kids going through college, coming out of college, to whom the Internet and the WorldWide Web is as natural a thing as television was to my generation, the baby-boom generation. Writing code is like editing film. We grew up on Howdy Doody. There is a whole group of people that may seem technically inclined to people who are older, but I don't think it's purely the MIS people that are on the Web. We are finding a lot of young people on the Web. I don't consider myself actually technical; I understand the technology and use of it, but I have never written a line of code.

Any other questions?

M: [Inaudible]

Larry Chase: The question is, how do I determine the value of my site for advertisers?

M: How do you charge your advertiser?

Larry Chase: Very conservatively. I will tell you, on WDFM, which logs-on weekly, we get between 3,000 and 5,000 people a week. Now, 3,000 to 5,000 per week is not like Netscape's Cool Site of the Day; WDFM will probably never have that many people. It's more like a business-to-business publication. It's more like buying a *Fortune* magazine. Even at that, we

charge a thousand dollars a month for people to get just a hit on the first page. We are not even charging — we don't even know, for example, the way people read WDFM. When they read a site they go out, then they come back, then they go to another site... They go out and come back. Every time they come back, we have no idea [they've returned] because they are coming back to the graphics that's already stored in their local computer. We give very conservative estimates for when they first hit and load the graphics of a site; those are the only numbers. We sell no matter how many people go back and forth — that's just extra gravy. Also, you have seen the banner. If you see it again in 10 seconds or a minute, is there another impression? You've seen the banner. We sell very conservatively, which I think is in our best interest.

A lot of people compare these CPM numbers -- they compare CPM with buying traditional print media. I remember a time five years ago when you could buy a 30-second commercial on CNN for \$500. Why? Because they didn't have the numbers in place. They didn't know how to measure. Once the numbers came in place, the ad rates went sky high. Intuitively, I know those people are out there. I am watching it. I see other people.

For \$500, how can you go wrong? In my thoughts, it's that kind of pricing [that's good], where I make the pricing of the site so attractive that it's a no-brainer so they can't afford not to do it. If you don't do it, your competitor might take it at that price. I would price my site very attractively because you're not just selling your ad site, you are selling a medium. You have to help them into selling the site. You might even have to help them with a marketing plan, and show them a promotion as we did with USA Data. Don't just dump them to your Home Page, give them something of value from your core business.

M: As a user, I am very aware of the agonizing factor of how long a graphic takes to load. Do your designers track how long it takes to design those graphics?

Larry Chase: It depends on what kind of site. It depends who you're talking to. If you are an insurance company marketing to middle America and they are dealing on Prodigy at 9600 or America Online at 14.4, you'd better make sure those graphics are lightweight. If you're more general and you are basically talking to other commodity people in the financial sector, people who are sitting on T-1, the big fat phone lines, you can probably up the graphics because you know that your target audience has the bandwidth to bring those graphics in fast. If it takes you longer than 30 seconds for this screen to resolve, you probably don't want to continue and you are not a likely prospect. You won't be interested, because it will be a very, very slow-load site. Maybe yes or no; I don't know if I agree with myself. I argue with myself endlessly.

M: You were talking about the CPM, and you said use the figure of \$20 per CPM. Could you just explain your CPM for the figures that you gave — \$3,000 to 5,000 per week, and you getting \$1,000 a month — how does that calculate?

Larry Chase: It's expensive. Mine is expensive. The question is, based on the CPM model, what are we charging at WDFM? The answer, off the top of my head, is that I don't remember. I think it's something like \$75, which is considerably higher than \$20; but again, it's like B to B, business-to-business publication. It's more of a qualitative buy rather than a quantitative buy.

When it's consumer goods like a car or an 800 Flowers, more people are apt to be qualified customers for that. You get volume savings because there are so many people out there when you are in a niche. If you go into those trade books, they get pretty defined because they are targeted to very hard-to-reach audiences. Again, \$1,000 a month in the overall scheme of things just isn't a lot. We look at it more like the cost of what a sales call would be.

If USA Data gets 10 people — you have to believe that out of 5,000 people a week, more than 10 people have clicked in there and maybe got in touch with USA Data. If they get 10 prospects out of that, then it's not the cost of advertising, it's the cost of sales.

M: [Inaudible]

Larry Chase: We saw that the Dutch site didn't do that. You had to denominate in guilders. There are various sites that only sell, and they say on their site, "Only within North America," or "Only within the United States and Canada."

Most retail sites that I have seen, like CD Now and PC Computing, are denominated in dollars because they expect to sell mostly, I think, to American and Canadian customers. That was the first European site that I have seen that denominated in another currency, because it's clearly aimed at Dutch-speaking people. I think the idea is neat enough put it in English and — using cybercash or e-bucks — to let me bid on that.

M: [Inaudible]

Larry Chase: How much are search engines charging? How much are they charging for specific words? I spoke to one company here at the show, and they were charging something like \$1,000 a word for a month with a three-month minimum. So if you wanted to buy the word "flowers" — you asked a very good question. I asked this specific question: If I buy the word "flowers," do I get "flower"? Do I get "flowery"? Am I buying the root or do I buy each word and every derivation? No, you buy the whole word for \$1,000 a month for a three-month contract. If you want to buy the word "flowers," you can buy that for \$3,000 for three months.

What some of the search engines will tend to do is mix it in. It's like churning butter. For example, with Hotel Discount on *InfoSeek*, he is up there with a six-month contract. He has a mix of about five or seven search words; normally you get five. You get a certain amount of search words with your basic buy.

If you buy half a million impressions a month, how many of those will be for the word "hotel" and how many will be for the word "travel"? Obviously *InfoSeek* cannot guarantee that half a million people next month or three months from now will ask for the words "travel," "hotel," "accommodations," or "reservation." He can guarantee that the balance that doesn't will be thrown into general rotation, so there's a general awareness of the brand out there. You can buy gross impressions. You can buy the word uniquely, or you can buy a picture, or both.

M: [Inaudible]

Larry Chase: As my lawyer says, that's not a question, that's a conversation. I don't know. It depends on each — the question was, what mix of budget between on-line promotion, direct-marketing promotion, regular newspaper, other media, off-line promotion — what mix is appropriate? The answer is, off the top of my head, that it depends on each individual situation. I don't think what 800 Flowers does is going to be nearly the same as what Liberty Mutual's going to do. Liberty Mutual will do a lot more industrial advertising in the trade books. They serve certain vertical industries. They probably run ads with the Web site in the books that they are already running advertising in, ones that supports that particular trade. How much do those books cost? That's an irrelevant question to 800 Flowers.

We are now out of time. Thank you.

WORLDWIDE WEB A RETAILING CASE STUDY: PC FLOWERS

SPEAKER

William Tobin

President, PC Flowers & Gifts, Inc.

William Tobin: Good afternoon. My name is Bill Tobin, and I am the President and Founder of PC Flowers & Gifts. I have been a technology entrepreneur for — I originally had 28 years, but I read it on the plane and did some numbers, and actually it's about 31 years, so I've changed it. The only disadvantage is you have to be 10 days older than dirt to say it.

All of the companies that I have founded fulfilled a niche in an emerging market for several years; in the case of PC Flowers, eight years before it became "en vogue." Their success has been based on the philosophy of offering a product or a service that is extremely unique, and at a level of quality and service so extraordinary that a consumer would not consider utilizing a competitive service.

I would like to think that my magnetic personality was the reason that I have been asked to deliver this speech this afternoon, but I acknowledge the fact that I am probably one of the few people who have a six-year, successful case study in the interactive marketplace for your review.

My goal this afternoon is simple. It is to pass along to you as much of the knowledge as possible, in order to have you avoid the mistakes that I have made — and the mistakes that I have viewed others make — in applying their products to serve the interactive market and the Internet.

I became interested in interactive marketing in 1987 and searched for a unique service in order to be part of this new and exciting industry. I co-founded PC Flowers in 1988, and went live on the Prodigy network in November of 1989. It is with great pride that I can state that PC Flowers has been named by many major industry and business publications as one of the most successful interactive providers each year for the past six years. PC Flowers has received numerous awards, but more important than the awards — and this will be near and dear to the hearts of capitalists — it has been profitable for five of the six years of its existence. That cuts to the chase.

Many of you small and medium companies can appreciate what I am about to say when I state that titles and perceptions change with the times. In the seventies I was known by large corporate America as a parasite. In the eighties I became a "value-added" partner. In the nineties I am Entrepreneur of the Year. I haven't done anything different; the only difference is in the mind of corporate America. Strategic alliances are now absolutely viewed as the way to go.

The era of strategic alliances has arrived with a vengeance with the era of the Internet. Many people are reluctant to change when things are going well; it's a business paradigm that has been in place for many years, and it's working. The old saying, "if it ain't broken, don't fix it," no longer holds.

The revolution in interactive marketing and technology has taken place and now dictates that you change in order to be part of this revolution. Be judicious, but do not procrastinate. That reminds me of a story of the ninety-five year old couple who went to their lawyer and said, "We would like to get a divorce."

The lawyer said, "You're ninety-five. Why have you waited this long?"

"We wanted to wait until the children were dead."

I urge you not to wait until your commercial child is dead or wounded. The Internet is like a train leaving the station: nobody knows where it's going, but you had better be on it.

Many people believe, as I do, that the key to success is to carefully form strategic alliances directly with strong technological partners in order to market your services, or to carefully form a strategic alliance with a gatekeeper or a marketing partner who will function as your marketing partner and gatekeeper for your particular product.

Once again, the key word is to form these alliances carefully. Alliances are almost tougher to get out of than a bad marriage. The decision as to which of these paths to choose depends totally on the strengths of your company's resources and the amount of these resources you are willing to commit in order to launch and support your on-line service.

Here is an example of what can be accomplished when an individual service provider forms a true partnership — boy, those are keywords. A partnership is the only way that it's going to work. When I first went on Prodigy in 1990, the first year we processed 24,000 orders, and that was considered astronomical at that time. Unfortunately, it's still considered pretty good six years later. This year, because of the partnership we have developed with Prodigy, we processed 30,000 orders five days before Mother's Day. It's an amazing, quantum leap.

I honestly feel that I am, at this stage of development of PC Flowers & Gifts on the Internet, exactly where I was in Prodigy in November 1989. I believe electronic marketing is in the embryonic stages of launching a metamorphosis that will change the present paradigm through which many manufacturers are marketing their products and services. I believe you are now witnessing the early stages of a shift to utilizing electronic marketing to bypass their traditional channels of distribution — i.e., retail and wholesale — and go directly to the consumer. This started in the retail industry when a company like Levi Strauss or Nike went directly to consumers with their own stores in malls right next to stores selling their products.

If you are a retailer, now is the time to ensure that your company is a part of this paradigm shift. If you are a manufacturer, it is imperative that you explore fully this shift and ensure that your company is in the forefront of this revolution.

I am constantly asked why PC Flowers & Gifts has been successful in the field of electronic marketing while many others have not been successful. I will attempt to summarize my observations. I feel that the same rules that I am about to go over for interactive marketing and on-line services also apply to the Internet.

PC Flowers & Gifts developed the technological infrastructure for customer credit card processing and order delivery from the ground up, so they support our interactive service only. The mistake I view over and over again are retailers and traditional direct marketers who dust off their present operation and try to place a square peg in a round hole and say, "This is our interactive offering." It doesn't work. Everything is different.

A strategic alliance with a marketing partner or a commitment on your company's part to develop a strategy for your product is absolutely essential if you are going to succeed. The consumer is more involved in interactive marketing than he has ever been in the past.

For example, the consumer error rate in the retail floral industry, when I started this company, was five to seven percent, and remains so today. This is acceptable in a paradigm where the consumer gets angry and calls your 800 number and complains, or he doesn't order from your catalogue or doesn't come into your retail store. You can develop an enormous marketing program and goodwill program over the years. However, you anger one interactive marketer, and he goes onto a chat service, and he basically can destroy you.

The capabilities and the power held by on-line consumers is awesome. Regardless of whether you have the best product, the best service, the best marketing program, the best prices, you must have a flawless process, a customer support and delivery system, in order to ensure your success and your ability to remain active. It's a very unforgiving industry. Interactive

consumers are far more demanding than traditional consumers, and service providers must offer a caliber of service and quality that is absolutely acres ahead of any other paradigm.

This is due to the availability of bulletin boards, chat services, and anonymity that cyberspace offers to these consumers. They also expect spontaneous service and response. A hundred companies have gone on-line and have all failed. Unfortunately, the number of services that succeeded are very small.

For instance, on Prodigy, the two most successful ventures have been PC-FM and PC Flowers. Interestingly enough, both of these companies were formed from the ground up to develop an interactive service. I believe that played a great role in the fact that they were two successful companies on that service.

I congratulate Alan Meckler on his huge success. I spoke at his first conference in 1994 and his second conference in San Jose. I think there were 20,000 there [at the second conference]; the first one had 10,000 and this conference, less than six months later, now suddenly I am told there are 35,000 signed up to participate, with another 10,000 floating through. In a couple years this will be a Comdex. I believe the Internet is worthy of all your thought processes and resources.

Two years ago, in marketing my services on the Internet, I had problems that didn't exist in the past. I no longer had the use of highlight screens, main menus, exit screens, PEM, all the marketing tools that I have come to rely on. I didn't have the ability to cross-pollinate all my promotional programs. I sat down and started to design the marketing tools and technology requirements that I felt would be necessary in order to produce a successful commercial environment on the Internet.

These tools that I developed were as follows: a totally secure order processing and payment processing, which could be used as a standard for security on the facility. Eventually [we developed] a secure environment for service providers as well as consumers. PC Flowers began taking secure credit card transactions in April 1995 utilizing Netscape, and will continue to work with companies such as IBM, Netscape, and many others on future enhancements to increase the security of our order processing system in the future.

I am constantly deluged with people asking me how upset was I when I heard about the Netscape break-in the first time, the second time. I simply say this: to the members of the press that believe negativism sells, give us a break. There's never been an industry that hasn't had minor setbacks that they hadn't overcome. I say to you, if as much money was being poured into cancer and AIDS research as is being poured into the security of the Internet today, we would not have those two diseases twenty-four months from now.

I also ask you to think about the last time you picked up an 800 number and called and gave your credit card number to an operator sitting who knows where, putting it in a database to who knows who, or the last time you gave your credit card to a waiter who went in the back room and did who knows what with it.

The perception of security on the Internet is completely distorted by the press. I further submit to you that if you have the unfortunate experience of having your credit card lifted, you are not responsible. Your maximum exposure is about \$50, if that, and most of the time it's nothing. The guys that are really exposed are the service providers who ship the product and don't get paid when the credit company says that it was not a valid transaction.

I believe you must earn the right on the Internet to present your commercial message to the consumer. You don't have a consumer that has agreed to have his mailbox invaded, and agreed to look at commercial messages by virtue of the fact that he has signed up to pay \$14 or \$9 per month for a service. I believe you must develop — I coined this phrase — “communities of interest” on various subjects such as gardening, cooking, sports, sailing, golf — what a person's interest is. Those are the necessary items to generate traffic.

One of the few pieces to the mosaic that must be put in place immediately, if a consumer is to utilize your community of interest, [is that] you must have earned the right to present your message. If a person is using my community of interest, which is developing now in gift-giving, I have earned the right to tell that consumer about a gift that is available on PC Flowers for that particular event or for that holiday of the year.

Unfortunately, my evaluation of the financial and the personnel environments to manually develop and maintain numerous communities of interest is difficult. It was out of my reach and out of the reach of most companies. I basically formed a strategic alliance with a company that had a global reach and had vast technological capabilities. It was at that point I developed a turnkey solution for my company on the Internet, not one where I would develop it as I went along. Before I went live, I would have most of the pieces in place.

After careful evaluation of numerous possible strategic partners, I chose to go with IBM. IBM agreed to build the tools which I would conceive of and help me create the turnkey solution to my Web site. They would have the ability to then take those tools and go out and sell them to other service providers, because what worked for me should work for everybody else. My problems are not going to be totally unique.

In addition to gaining the use of these remarkable tools, I would benefit from the creation of an umbrella which would enable my service to reside with other service providers in the same IBM Web server. This technical umbrella would provide the one-stop shopping environment that I believe is attractive to consumers on the Internet. This umbrella would also provide me with marketing partners with which I could develop cross-pollination programs and start to duplicate some of the efforts that I have been doing over the past six year in on-line services.

Basically, for the past two years I have been thinking of tools and I have been thinking of content. The last thing on my mind that I was concerned with is graphics and navigability of site, because I knew that we were not going to have traffic in the sites until I got the tools implemented.

For the past two years I have been developing the content, and when I completed that development and the tools one month ago I retained one of the premier design firms for interactive design in the world, Magnet Interactive Studios in Washington, to completely redesign all the graphics and all the navigability. It will be event-driven rather than category-driven. We will use push-pull through Netscape as opposed to using these hexagon boxes, and that was my creation. In the first meeting they said, "Whoever thought of hexagon boxes?" So it's going to be replaced.

My first category is problems I have had for the past six years in shipping flowers to 161 countries directly through the FTD Mercury Network in the United States. I use only 7% of the FTD members who contract to me and operate according to my quality control and delivery requirements. We have our own order processing center in Downers Grove, Illinois, where we download from all on-line services on the Internet. We do the credit card processing, and it goes directly to my preferred vendors.

I have broken all the categories down, and I will just quickly give you an idea of what they look like when you go to them. We have a graphic in order to avoid the problem that most people who order their flowers by calling a local florist have — they have no idea what they look like. They have no guarantee because the local florist isn't responsible if something happens at the other end. If your credit card goes back, it's not deliverable.

Through our service, basically we tell you within an hour if there is a problem with your credit card. If you visit your mom on Christmas, the flowers — if the ones we sent you weren't really fresh for Mother's Day, we send a dozen roses. If the order isn't delivered, my preferred vendor calls the daytime number of the recipient, and we figure out how to get it to you. In

addition, most people think there is a tremendous premium by the fact we are considerably cheaper than the local florist.

The next paradigm that I recently developed this year is what I believe everyone has ignored, which is the fact that growers who supply wholesalers who supply retailers had a burning desire to go directly to the consumer. These growers are bigger. They arrive nine days fresher and considerably cheaper.

What I have done is develop this first program that you will see here. I have been testing it for over eight months, and I can tell you that the prices are incredible. There are still reasons why local florists have advantages. Due to the fact you get an order into my network by 12:00 midnight, we can deliver the next day through the Mercury Network. I can't do that through growers. I can't ship arrangements, other than the cut flowers, through the grower, because everything's going to FedEx. FedEx has a chute that every product goes through, which is hard on the flowers.

The next category is stuffed animals. We just developed a whole line of stuffed animals, plush animals. We developed a whole line of plush animals for events, with costumes on them and so forth.

The next category is gift baskets. It's a tough category; this category is very difficult to fulfill, because you need a large company who is ready to ship a real diversification of products within a few hours. We put together East Coast baskets, West Coast, ethnic baskets for the Italians, etc.

The next category... I feel that in the 90's the commodity will be time like the commodity was money in the 80's. I want people to be able to come and set their table from soup to nuts and not pay more going to Hickory Farms or a catalogue. It's succulent: fish, poultry, desserts, specialty products, nuts, etc. So if you decide, for instance, that you wanted to have a seafood dinner and you wanted smoked salmon or salad to start off with, you plug that in. Then go back and say, "Okay, we want this for dessert. We might want something unique. Let's pick something like ice cream truffle for dessert." No matter what you choose, it arrives in a temperature-controlled container the next day at your front door, and you have your dinner party with no additional expense than if you bought through catalogues.

The next category form was PC Balloons. I created PC Balloons. My delivery infrastructure is my retail florists, but we ship one balloon arrangement for every floral arrangement.

The next-to-last category... I had a desire to be able to duplicate the 10,000 Create-A-Card kiosks that American Greetings has throughout the United States, [and put it] on your PC. Heretofore, the only way you could send greeting cards was electronically to people's mailboxes, which works if the person has a mailbox, and if they were on a network. But my mother, and probably your mother and many people you know don't have a mailbox.

So with much work over the past couple of years, my marketing partner of choice for this category was American Greetings Company. What we have done is that we have duplicated American Greetings card kiosks on a Web site which allows you to bring up a greeting card. You can go in and say, "When I am finished with this greeting card in a nanosecond, I would like you to print it out in Cleveland, and I would like you to put it in an envelope, put a stamp on it and address it for me and have it arrive by U.S. post office within a few days, the same as if I did it myself." You now have that choice.

By the second quarter of 1996 I will give you a second choice, which is basically to say I would also allow the extra, "and I would like the card to arrive with my gift basket, with my Teddy bears, with my flowers, with my gourmet food gift, at the same time." We will be placing [this ability] at Create-A-Card kiosks and Hickory Farms, those two locations there, and at the grower.

I also felt, because of the vast [number of] consumers on Internet — IBM has given me the capability, through electronic tools, to avail myself of unlimited communities of interests with very few people. These tools have the ability to reduce the head count, which is necessary to perform this sale, this customer support, and to basically reduce the support by 75% over a telephone paradigm.

I have also designed nine invasive marketing tools, such as the gift reminder, which reviews very effectively for the past six years and allows you to have your choice to remind yourself of various holidays and for custom events. That gives me the unique capability of having your permission to go into your mailbox to remind you of various events.

Flowers and gifts are very unique. Time and time again, we have partnered with various companies in on-line services who send personal digital messages to the consumer. We have the consumer come back saying, "Don't you do that again." When we send a message reminding somebody that it's Christmas, Mother's Day, Secretary's Day, whatever the case may be, that they can send flowers. Flowers are like mom and apple pie. Nobody gets angry.

The next area is that you provide communities of interest on various subjects. The electronic technology tools which IBM designed allow me to go through all the electronic informational services on the globe and bring back the most frequently-asked questions and answers on a regular basis.

For instance, we have said that people wanted to know about roses. We have developed the tools, and given it parameters to go out and find the most frequently-asked questions and the answers on the electronic sources of information on roses. If you wanted to know about a particular question on diseases on roses, you would be able to get these answers on these diseases.

The next and biggest problem on the Internet is traffic, and how to get people into your site. How do you get them there? I simply asked myself, "What has made us successful on the on-line services over the past six years?" It was really very simple. All we did was get a highlight screen, main menu, and an exit screen to remind people what the next month's holiday was, and allow them to jump from that icon directly into our service to place their order.

With all that in mind, why don't I develop a program? I will call it "The Internet Consumer Incentive Traffic Program," where I will take a year's worth of GIF files, place those GIF files at an address, and I will go to the largest Web sites — I would place those GIF files in one address, and I would allow our marketing partners, who would be the largest Web sites on the Internet, to be able to go to that address on a monthly basis and be able to pick the GIF file size and style that fits their particular availability on their Web page for that month. So if it's December, my partners will go to this file and view all the GIF files that I have got available, and they will choose which of the GIF files best fits their style for that particular month. Underneath the GIF file they will then develop a program that is unique to them; maybe they have a membership acquisition program that month, or they want to get you to view a screen or perform a service or function within their site. Or [perhaps they want to] develop promotions — like a dinner for eight for that particular holiday, flowers for the whole year on every major event, or \$5 cybercash due upon anyone who does this for our marketing partners.

We then allow the consumer to hyperlink directly from this GIF file to my Web site. We assign an electronic token automatically to that consumer, which tells us where that consumer came from. When that consumer shops, the token drops, and we identify which of the on-line services were Web browsers or sites that sent consumers to us, and at the end of the month we compensate that Web site with a percentage of the sale.

These tools have been developed by IBM over the past year and the entire program is presently underway. I believe that this ability to cross-pollinate traffic is the future of the Internet. There is no one that's large enough to stand alone on the Internet; you must develop

marketing partners. We tested this program on Valentine's Day last year and on Mother's Day with Prodigy, Mecklermedia, and *Pathfinder*. You will have an opportunity to listen to Bruce Judson after me about *Pathfinder*; after I am finished, Bruce will tell you about one of the most successful Web sites on the Internet. To date we have 32 marketing partners we have developed, and the tools will be completed at the end of November that coincide with the redesign of our Web site, maybe.

I feel that the categories we have got are absolutely the very best. Basically, I hope I am able to develop a clone of PC Flowers with PC Flowers & Gifts on the Internet. We have expanded our initial concept of the floral arrangement, because I believe I must continue to go to the next level, no matter whose chain you rattle. I was not elected the most popular guy by the retail floral market; however, it's my responsibility as a financial marketer to give the option to the consumer and to develop the paradigm, make it possible, and give him the choice. If I don't, somebody else will.

We will be adding additional categories throughout the years. I believe the six years of interactive expertise that I have gained through PC Flowers and the vast technology of IBM and the marketing partners that I developed will help me to secure a successful commercial environment on the Internet.

The tools which have been developed from my turnkey solution are now available to you through IBM and various other companies that have developed and could work for you as well as they work for me. You have a choice; I will be demonstrating the turnkey solution at the DMA conference in March, and also at the next convention in San Jose. You don't have spend two years developing them.

Thank you for the opportunity to present this speech, and now I will take questions and answers, and the best question gets to send a dozen flowers, and the worst question — well, I'll tell you that later. Thanks for your time.

M: Do your marketing partners have exclusive arrangements with you?

William Tobin: Yes, they do. Do my marketing partners have exclusives with me? Yes. I have spent too much money. You shouldn't put all your eggs in one basket.

M: What kind of feedback did you get from your florists when you opened this new service with the growers?

William Tobin: What type of feedback did I get from the retail florists when I opened up directly from the growers? Well, they loved it. The retail florist paradigm is that FTD had 85% of the wire service and now it has around 40%. Basically, the rest comes from supermarkets who are using the grower, and also comes from electronic marketing. It comes from all these alternate services that are available to the consumer. Everybody is arguing over that same eight-inch pizza in the wire service business, and in some ways it's better. The consumer must have a choice.

M: [inaudible]

William Tobin: Is my product offering restricted to U.S. buyers? Yes and no. I can't ship fruit or food overseas. Yes, from the standpoint of view that I can take a floral order today, and I can have it to any country in the world, 160 countries, tomorrow. That opens a new opportunity. One of my marketing partners is AT&T Interchange, and we were just discussing at a meeting this morning the opportunity for business-to-business applications where they're marketing

their services to businesses. One major brokerage spent \$7 million on flowers. Business-to-business applications for florals and gifts is enormous.

I am one of the few companies in the world that can take an order from you today and have it in China tomorrow for a \$15 service charge. Your alternative is to buy the gift, fill out the papers and ship it FedEx. We give you the ability to ship overseas.

M: [inaudible]

William Tobin: The on-line services traffic is enormous. On the Internet I wasn't concerned about traffic. If you are concerned about traffic — put traffic behind you, don't even think about traffic. Don't think about sales. Develop your technical processing and customer support. Develop your categories. Develop your content, develop navigability, then graphics. Then worry about what your traffic is. Forget about traffic. Right now, for most people, the Internet is not a commercial environment for speed. I believe within 12 months that speed will be a non-issue because of the ADSL, which gives T-1 capability, cable companies to give you access, N-12 speed. It will be a non-issue.

Second is security. Within 12 months, and probably much sooner, security is a non-issue. Once those are out of the way, if you are there first, and you have spent the time building strategic alliances, building the best services and best content, then it's time to start getting traffic.

M: What kind of investment did you make to have your pages done, and what do you see as your return on them?

William Tobin: What was my investment to Magnet Interactive Studio Services and what was my return on my investment? Magnet would be very angry if I told you what I paid for it. It ain't cheap. If you go with the best, you get what you pay for. However, I think it was reasonable based on what they are bringing to the party.

What is my return on investment? Since my investment bankers are sitting in the audience, phenomenal. It's there. We got it back already.

M: What was the biggest mistake you made and how did you correct it with PC Flowers & Gifts?

William Tobin: I made an error in November 1989 when I set the company up and I didn't know that 93% of the FTD members were not capable of delivering to a quality that was required by an on-line service because they are in that 5% to 7% paradigm, and unfortunately I went live with 55,000 members on Prodigy with four items. One week into it I was called in by IBM and Prodigy and they said, "You'd better fix it or get it off." I didn't know that the smaller florist buys X amount, and when they run out they shut their Mercury machines off. When they run out of a container, they switch.

You are in a paradigm of "what you see is what you get," and you'd better know that your suppliers are doing what they have agreed to do. I had to quickly — I mean in thirty days — get on a plane, and I flew all over this country, networking all the major florists in this country. I got the top seven of the FTDs, which gives me coverage through every city in the United States, to agree to my terms and redo it, and I had to develop an infrastructure that allowed me to cut out the other 93% of the members. I said, "Wow, I should have stopped at 12 companies. This is a disaster." We did it.

M: What are the criteria that you use to decide which service providers are better to work with than others?

William Tobin: By “service provider,” do you mean category or by the platforms? AOL —

M: Platforms. I was wondering if you could give us more details on how you made those choices?

William Tobin: The question was, which service providers should you work with, and can I give any help in choosing the service provider? I made the conscious decision about a year and a half ago that it was not economically feasible for me to maintain a service on AOL, Prodigy, CompuServe, AT&T, Microsoft and the Internet. I made the decision that I would develop a killer Web site, utilizing the best designer in the country, utilizing the most innovative marketing technology developed. By utilizing the best designer in tracking, and database management tools developed by open market systems, I would develop the premier service of flowers and gifts. Most people don't realize that flowers represent 28% of all on-line transactions. Most people don't realize that the cut flower market last year was \$15 billion in America, twice the size of the Yellow Page industry and twice the size of the cellular industry.

I would try and develop a link to those services as opposed to — it's not feasible to change your product into all different codes for seven different services. I can't do it. Maybe you can if you have one item. The key is you have to develop a killer Web site. [Thank you.]

WORLDWIDE WEB EFFECTIVE MARKETING ON THE INTERNET: A PUBLISHER'S EXPERIENCE

MODERATOR

Ken Lane

WWW and On-Line Information Consultant

SPEAKER

Bruce Judson

General Manager, Time Inc., New Media

Ken Lane: Welcome to all of you here. Just to establish some format for this afternoon's session, we will have our presentation first and there will be plenty of time for questions and answers afterwards.

We'd also like to remind you that there is a CD being produced for the proceedings of the entire conference with audio tracks for each of the sessions. You can probably get more information about the pricing and availability of either of these two items by [going to] the administration area on the second floor.

And now I'd like to introduce our next presenter: Mr. Bruce Judson. He is the General Manager of Time Inc. New Media, a division of Time, Inc. His responsibilities include developing *Pathfinder*, Time-Warner's home on the Internet, which was launched in late 1994 and is now one of the highest traffic Internet sites in the world.

He is also active in creating interactive marketing applications for the Full Service Network, Time Warner's information superhighway.

Bruce is the author of *Effective Marketing on the Internet*, a cover article in the Summer, 1995 issue of *The Advertiser*, the magazine of the Association of National Advertisers. He is in the process of writing *Net Marketing*, which will be released in the spring of 1996 as part of the best-selling [Net Book] series produced by Random House. He is also a frequent speaker at industry conferences on multimedia, and is a member of the Board of Directors of Open Market, Inc., one of the leading suppliers of software on the Internet.

Bruce is Vice Chairman of the New Media committee of the Magazine Publishers of America Association. He's also Chairman of their task force on Internet ad measurement, [which is] leading the industry's effort to develop appropriate Internet advertising standards.

Earlier in his career, Bruce served as Director of Marketing for Time, Inc. magazines and Director of Target Marketing for Time, Inc. Prior to joining Time, Inc. Bruce was a manager of a Boston consulting group. While there, he helped to found the New York office, and was a leader in developing the firm's consumer marketing practice.

He has a Law and Management degree from Yale and was Senior Editor of the *Yale Law Journal*. [He was also] co-founder and Editor-in Chief of the *Yale Journal* on regulations. Bruce is a member of the New York Bar Association and a 1980 graduate of Dartmouth College.

He's quite a guy! I'm sure you're going to enjoy his presentation. Without further ado, ladies and gentlemen, colleagues, Mr. Bruce Judson.

Bruce Judson: Thank you. I'm not sure even my mother could give that complete a description! It is a pleasure to be here. It's a particular pleasure, and particularly exciting to me, because we have recently reached a milestone for *Pathfinder*. Last week was *Pathfinder*'s one year anniversary. For us, it has been quite a year.

A year ago I never [would have] thought that if I said to people, "well, what I do is run a site on the WorldWide Web" that they would know what I meant, much less that they'd be interested in talking to me and that I'd be popular at cocktail parties.

It gives me a real sense of how far the Web has come and what kind of extraordinary evolution has taken place within the last year. What I want to do today, very briefly, are two things. First, really, is to show you a little bit of where we've come with *Pathfinder*, and a little bit about where we're going, kind of as a media product and as a facilitator of commerce on the Internet.

Second, I thought I would give you a brief overview of some thoughts about how we see marketing and commerce developing on the Web.

Again, marketing and commerce, like *Pathfinder*, are something that not only did not exist a year ago, but I would say that the notion of advertising as a form of marketing on the Web virtually didn't exist six months ago.

Yet today we have companies — there's a whole host of exhibitors in the hall — that have businesses built around ad measurement. They all accept that this has become a business and that there's something going on here. I want to talk a little about that and also about how we see it evolving.

As I said, *Pathfinder's* evolution has affected several key initiatives. We launched *Pathfinder* a year ago with four content areas: *Time* magazine; a product we called the *Virtual Garden*, which drew content from Time-Life Books; and *Sunset* and *Southern Living* and other Time, Inc. properties, [including] *Live Magazine* and an area from Time Warner Electronic publishing, which is Little, Brown, and Warner books. It was essentially launched as a grand experiment in electronic publishing. After the launch, what I would say the most striking thing was is that we quickly realized we liked what we saw. We liked it from two perspectives.

As an information source, as a journalistic company, we were excited. Our journalists were excited because they were looking at the Web and thinking, "this is another creative place; this is a place where I can do something different, where I can exercise my creativity, my responsibility to society, provide information and entertainment. We can develop this new medium to really be something."

We were also excited because our own kind of excitement with the media was validated by the Internet community. We were immediately popular. As was said in the introduction, *Pathfinder* is one of the single most visited sites on the Internet; we are at approximately 17 million hits a week and are continuing to grow at quite a dramatic pace. It's also worth noting that one of the things that we're kind of excited about and proud of is that this is all pure word-of-mouth. We have not promoted the site in our magazines and we have not done any advertising. This is just pure Internet phenomenon at work, building this popular site.

All right, so what does it look like today? This is essentially what *Pathfinder* looks like today. What we've done is made a decision. In early 1995, as I said, we put it out, and it was an experiment. We looked at it and we made a decision in early 1995, and we said, "we are excited, we're going to build this out as a commercial product." That build-out reflected three phases.

First, we decided that we were going to broaden and deepen our content. Those of you familiar with the site know that at this point it runs about 70 distinct areas. I'll show you a couple of them. They represent an incredible collection of interests — some of the most familiar icons in America today. I'll talk a little about where we're going with those.

Second, last spring we said we want to understand more about what's happening here. We launched Registration First, and we also launched ad sales.

What is remarkable to me, as I've said before, is that when we launched ad sales there were questions [such as]: Would the Internet community accept paid advertising? There were issues. How would we be accepted? Would we be blamed? All those kind of notions. I'll talk about how we felt about that, what we saw and what we see coming in the future. In fact, we

did it the way we felt the Internet community would accept it, which is that it was non-intrusive. We view advertising within high-traffic media sites as a non-intrusive invitation for the consumer to come in and visit that advertiser's site.

It's just like a magazine, where a consumer can say "I'm interested" or "I'm not interested." They can accept that invitation or choose not to accept it. By building it out in a non-intrusive way, which we felt was very consistent with the Internet community and the ethos of the Internet community, it was quickly accepted. In fact, it's popular. I'll talk about that in a little bit.

Finally, we've said that next year we are going to start charging for aspects of *Pathfinder*. Ultimately we believe that, as a publishing company, this is a dual revenue stream vehicle.

As I said, this is a partial look at what is in *Pathfinder*. It's everything. It's a little bit tough to read from *Time Daily*, so it's an opportunity for *Time* magazine to move from weekly to daily journalism. There's *People Daily*, which is a critical read for many people; *Money Magazine*, which is all about personal finance; and the *Life* photo center, which has a really terrific area on the Beatles right now. [There's also] *Sunset*, *Southern Living* and *Sports Illustrated*. What I think is important, though, is that these are not simply magazines on-line. Our vision, and the way we are moving *Pathfinder*, is to serve readers' interests on-line.

An interest in personal finance, an interest in sports — it's our goal to ask, "How do we serve that interest on-line?"

Now, that may mean that you have access to the magazines. It may mean that portions of the magazine are hyperlinked, re-edited or re-purposed. It also means that you're probably going to want to have applications that are specific to personal finance, to sports and so on. We've found that people are interested in talking to with experts, and editors are seen as experts. So, we are moving to say, "these are distinct interest areas, and they are anchored by some of the greatest, most familiar and best put-together information pieces and icons in America."

But they are something distinctly different, and I think over time you will see that difference. The interactivity which is increasingly being facilitated by the Web will become even greater. In fact, we start to do things — like our sports area is now called "Sports from *Sports Illustrated*," because we want it to be clear in the consumer's mind that this is a very special, exciting interactive application built off *Sports Illustrated* and *Sports Illustrated's* creativity.

All right. Over time, I think what you're going to see is deeper and richer material. There will be more figuring out what people want on-line as we serve those different interests, as well as bringing up additional interest areas.

What I want to do now, actually, is shift our discussion. Let's move very briefly to a discussion of the evolution of marketing and commerce on the Web.

What I think is that there are a couple of things that have happened. In a sense, the first phase of the Web media and marketing on the Web is now very well along. I'll talk about that in a second.

In fact, what's also happened is that the Web has been recognized as the place for marketers on-line. What you see moving around those circles are America Online members, Prodigy, Internet MCI, Microsoft Network, and now AT&T WorldNet and eWorld and Delphi. Essentially, if you are a marketer and you put up a Web site, anyone who is on-line can read you from anywhere. That is not true if you put yourself on a proprietary service. That is one of the essential reasons that the Web has caught on so quickly as a marketing vehicle.

We think it has very clearly become the place on-line where, if you're a marketer, you go. It's also got all kinds of advantages if you're a marketer. One is that you control it; no one owns the Web. You can put up whatever you want.

You can change it anytime you want because there's no one that's setting ground rules. You know, I used to think that was a problem; this is chaos, nobody sets any rules here. Then I decided no, this is the great strength of the Web. It means that people are constantly experimenting for what is interesting, for what is going to move people. It is constantly rising; there's nobody setting rigid formats.

What you see is terrific marketing: getting an audience, moving forward. As you would expect, there's also a lot of yucky stuff, really awful stuff, and people don't go there. And that goes away.

So the unruliness of the Web, in a sense, has made it a hotbed of marketing experimentation. That is one of the great things about it. There's also no charge. If you are a marketer, you're typically used to thinking in terms of, "What it's going to cost for fifteen seconds? What's it going to cost me for thirty seconds on a medium?"

This is exactly the reverse. There's no limit in terms of time and space for what you pay. There's no cost in that sense; there's no media cost. And you could, in theory, easily put up thousands and thousands of pages. So you have an entirely different challenge.

That challenge is: How do I create something that is engaging, that holds a consumer? The consumer comes to my page. If I'm not exciting, if I'm not interesting, they're gone. But if I can bring them in, if I am interesting, if there's some information that they want about me, they might stay for a half hour, or whatever the appropriate amount of time is. It's an entirely different way of thinking about the media. It's no longer, "what can I do in the limited amount of time or space that I have?" Given no constraints on that, it's now "What can I do that is interesting, that is helpful to the consumer, that the consumer is looking for?"

All right. As I said, about six months ago we would have said there were probably 20 or 30 of the top 500 companies that had Web sites. They were probably very technical and not consumer-oriented.

Today, a quick look says that about 25% of the top 500 companies in sales have established marketing-oriented Web sites. People are moving quickly to get into this environment. I would also say that if 25% of the top 500 are up, at least another 25% of the top 500 are in development. They'll probably be up in the next three or four months, because virtually everywhere I go people talk about how they're about to turn on their Web sites.

This is very quickly becoming a mainstream strategy for the nation's marketers. As you would expect, it varies a lot by category. So far, 50% of telecommunications companies are up, while the numbers for automotive and travel are smaller. Certain packaged goods products are even smaller. We think that over time all of the different product categories are going to move into the Web, particularly as the Web audience broadens from what was a technical base to a much more mass base. Throughout 1996 there's likely to be an increasing number of sites established.

Why has it been such a popular thing? Well, I talked about the ability to experiment, but that's the marketer's perspective, not the consumer perspective. What is it, if you're a consumer, that makes the Web a great marketing vehicle?

We think it's a couple of things. I like to say it is the world's greatest 800 number. By that I mean: You've got someone sitting at home. Let's say you've got the typical American [home]; let's say a two career family, kids, overworked, tired and not enough time. It's 10 o'clock, it's the fall, we haven't planned our holiday vacation yet — we'd like to do something. What are the family's options?

Well, they can pick up the phone, dial an 800 number and call for some brochures. They have to wait for the brochures to come, though, and they have to find the time to look at them, think about what they want to do, and then make the decision. So, they have to wait for both for the delivery and then be back together in that buying or shopping mood.

Alternatively, they can go onto the Web, visit the Club Med site, gather in-depth information about each site and find out which site meets their personal needs. Increasingly, sites are geared toward telling you how to find things that are relevant to you personally.

In this example, let's say [the family wants to decide] which Club Med is good for kids. They can make a decision about where they want to go, and in some cases, depending on the site, actually reserve on-line or at least know what they want to do and then pick up the phone and make that reservation. Within an hour, somebody can go in, investigate a product on an in-depth basis, and make a convenient decision anytime within a 24-hour period.

It's a storefront that's always there. That's also something that people talk about a lot. Americans are living, working and doing things at different hours. The ability to shop, get product information, interact — or whatever phrase you want to use — at any time of day or night is also incredibly valuable.

Consumers do buy things. They want to know things. The Web is an opportunity to give consumers in-depth product information. They can get it at home, which they like. They control it; they like that also. People talk to us a lot about concerns [regarding] talking to intermediaries. There's a group of people today that want to increasingly educate themselves before they go out into the world and start talking with agents and others. The Web gives that ability.

It is also the ability to have a real interactive sales environment. You can say to somebody — someone can come in, say, to an insurance site. It might say, "What kind of insurance are you looking for?" You might say, "I'm interested in life insurance." It might ask "What kind of life insurance?" The person might respond, "Explain the differences to me."

You can take a complex product, which normally requires a very long sell with a person, and if you are marketer and can think out the questions, what the different paths are that people are likely to move down, then you can anticipate those questions and create choices. You can move someone down that tree-and-branch architecture and actually bring them very close to a sale.

I do want to make the point that you can also reverse that. It might not be the kind of insurance you are looking for. "What kind of person are you? Have you recently had kids? Are you recently married? If you recently had kids, here's the kind of insurance we recommend for you. You should have disability [insurance]; you should have life insurance."

"Oh, tell me why, what's an appropriate amount? What kind do you recommend?"

People do want that kind of recommendation function. They know that it's coming from someone who wants to sell them something, but it doesn't matter; they are still interested, particularly when it's presented in an appropriate way where they feel they're getting good information.

It's an extraordinary consumer convenience. It really is the bottom line. I tend to look at this a lot — and we'll talk about that in a minute — like an ATM. Ultimately, the ATM skyrocketed because it was a good consumer interface. It was extraordinary convenience, and that's really what marketing on the Web, and shopping on the Web, are all about.

It is the ability to create a one-to-one relationship with the consumer. You can begin that dialogue with the consumer. The more you can anticipate what a consumer is going to be interested in or asking, the more you can make that dialogue relevant to the consumer.

There are also some really interesting things going on in, kind of what I'll call "one-to-one" or "dialogue" marketing. I'll give you some examples of that in a second. We'll talk about how we think it's going to evolve.

Now, what is also fascinating is when you asked me six months ago, "What is marketing on the Web?" I said some of what I said to you, which is that it is in-depth product information. It's ultimately going to be the ability to sell someone something. In fact, what has quickly

happened is it has become much more than that. Marketers today, companies today, are doing a whole range of things that I kind of think is worth really noting.

They're doing things to build their brand; they're actually creating an image on-line. The Ragu site, which is the Mama Cucina's Ragu site, is very famous. What they've done is positioned that brand as an Italian product. In it it says, "learn how to speak Italian." It's really given it a sense of life and image.

Ben and Jerry's has gone off and said, "We're a fun place." Snapple has a very distinct image on-line. So people are really using the Web to build brands.

If a consumer dials into you through the Web, you don't have telecommunications costs, so people are saving and will continue to save extraordinary sums of money. You don't have the 800 number calls and you don't have the personnel costs associated with that 800 number, so when you can move to an order-taking system on-line, on the Web, it's a huge savings. It also can be a vehicle for more effective and low-cost customer service. And that's one of those win-win situations.

Think about customer service. I call; if there are not enough operators I either have to wait or it's really — you know, there's always enough operators and it's more expensive for the company. What happens is, in the right case, I can go on-line. Again, no 800 number charge [to the company], and I don't have to wait. And if it's a good interface I can go in, find out what I want and get taken care of. I'll show you an example in a second.

There are companies that are literally saving millions and millions and millions of dollars by providing customer service through the Web. They're also providing a more effective customer service than they were through the phone. People are beginning to do sophisticated promotion and building databases and potential customers that they can deal with on an on-going basis. That's kind of interesting. I'll show you an example of that.

Really, I kind of think, what is the ultimate? The ultimate, or one of the ultimate things, is if you can think, "What is my product? I have this product. Is there something that I can do on the Web that actually makes my product more valuable to somebody?" And there are, again, examples of that starting to emerge. People are actually using the Web to make their very product better. And finally, you can use and create intelligence as I talked about, those one-to-one relationships. I'll show you some examples of that.

All right. What I'd like to do now is go through a couple of examples that can give you a sense of some of what I've talked about, a hint of what the future will be like for marketers.

Customer service has been one of the central competitive battles, if you will, of the early 90s. What I really mean is that people have come to expect extraordinary service. If they don't get extraordinary service, they go somewhere else.

A well-known customer service example for those of you — and for people who are not familiar with it — is Federal Express. You can go in, type in the ID number for any package that you have in the system, and it will tell you where that package is. Is it in transit? What happened to it? When can expect arrival?

That's all an automated system. So again, I think it's safe to assume that FedEx is both saving millions of dollars on people who are no longer making phone calls, and they are providing a superior service. Because, you know, I don't have the hesitancy of calling. There's still a thing of people don't like to bother other people. There's a feeling of bothering people when I get on the 800 number and [ask], "What's happened to my package?" There's not that hesitancy here. And again, there's no waiting, in the event an operator's not immediately available. It is instant service.

This is an example, to me, of the really interesting promotion, database building, creative activity that's going on in the Web. The Cathay Pacific site has recently launched a business

class service from Hong Kong to L.A. What they said is, "We're going to have an auction, no minimum bid, for 50 seats over the Thanksgiving vacation — round-trip, Hong Kong to L.A."

So what's going on here, from my perspective as a marketing analyst? First, the creativity was really interesting. I saw auction and I thought, "Wow, that's kind of neat," and it drew me in.

That's one of the things that I think people increasingly need to focus on. What kind of creative icons are going to draw people into the site? Once I came in, it read, "You can bid." This is impossible to read, but it says, "You have to register, and when you register, then you can bid."

All right. What's going on? You kind of figure that anybody who bids any significant amount of money is a real customer. They are somebody who is interested in going back and forth on this to Hong Kong. Now, Cathay Pacific knows who they are. They even know, kind of, a little bit of assessment, what someone's willing to pay to do that. When you register, you give them your e-mail address, and they do say they may contact you in the future with future offers. I think that is a critical thing, in a sense that this is a kind of direct marketing, but the dynamics are entirely different.

The dynamics of direct marketing are typically: what's this going to cost me to do this mailing; and, is it going to pay out on its return? Well, here, if I know someone's e-mail address, it's a cost-list mailing. But the last thing that people want is junk e-mail. I think that is one of the central etiquettes of the Net. Don't send something to someone without their permission.

People, when you talk about privacy, have a very strong sense of wanting to maintain their privacy. But when you register for Cathay Pacific, they're very up-front. They let you know about specific offers they may have.

I would also say that if you bid some significant money to travel round-trip to Hong Kong, if they have a special promotion or special offer to Hong Kong, you're going to be interested in it. You're not going to be upset to receive [the information]. So what are they doing? They've created some really interesting ideas; they're building a database of prospects, they are experimenting with a new form of sales.

That's something else that the Net may ultimately create. There are a lot of products for which prices fluctuate. Auction sites are beginning to develop on the Net. If you start to think, "I suddenly have a pure market of millions of people who are looking to see what's available and people who want to sell things," then auctions may actually become a means of sales, as a mainstream sales vehicle. I don't know; all I'm saying is that it's possible. This is both a promotion and, in my mind, an experiment with that kind of new potential sales vehicle.

All right. Another issue: Why hasn't there been more buying of stuff on the Internet? What happened? This is "Shoppers' Advantage," but you may know them as Citibank Shoppers' Advantage. They tend to partner with credit card companies. You join for \$49 and then you can buy up to 250,000 name-brand products.

They've recently gone on the Web, and there are a couple of things about this I think are exciting. First, again, no telecommunications costs. It used to be you called an 800 number. Now I go in and they're not bearing that cost anymore. If you are familiar with this service, you call up and you say, "I'd like to know about this microwave and it's this brand." And you tell them what you want to know, they tell you the price, and you say whether you want it or not.

Typically, people have a thing about, you know, "well, how about the next price up, the next price down?" There's a kind of human reticence to keep someone on the phone to say, you know, "I want to know about every possibility."

When you're on-line, and I actually went through this, I found myself saying, "I went in to see how it worked," and then I said, "Well, what if I want that television. What would I have

to pay for the next one up, and what would be the features? How about if I wanted to pay less?"

That kind of hesitancy is a human feature. Without costing the company anything because of an 800 number cost, I was able to really check out all my different options, and I could feel better about the decision I might be making to purchase. In that sense, I would argue very strongly that what Shopper's Advantage [provides] on the Web is a superior product to what they do by offering you a catalogue with a limited number [of items].

And necessarily so, because you can't put 250,000 products in a catalogue and then have you phone in your order. The Web actually allows you to create a better, more consumer-friendly, effective product. And the other thing I think is important, before we leave Shoppers' Advantage, is that the Web is a terrific source for information. We'll talk in a second about transactions.

A lot is not being bought on the Web. There hasn't really been a lot of stuff to buy and there haven't been brand names. Brand names are an indicator of trust. You kind of think of GE, or whatever kind of brand name resonates with you, "Well, if they're there, and I can get that, I'm not worried."

So bringing on CUC which has brand name products, as well as others that are coming on with brand name products, is going to make a significant difference in the evolution of actual purchasing on the Web.

This is, to me, one of the most interesting sites that's come up. It's a bookstore called amazon.com. They sell over a million books. Their discount — they have some pretty significant discounts, but that's not what's most interesting to me. What's most interesting to me is they've created what they call, "Eyes and Editors," which is a personal notification service.

Eyes is your fully automated, totally customized book. It's a highly anthropomorphic search agent, and it can let you know whenever there's a release of new titles that will be of interest to you.

So, what's going on here? You come in, you register for Eyes and you say, "You know, these are the authors I like, this is the kind of book I like, these are the kinds of books I like." And if they've got those authors, when that author comes out, they'll send you an e-mail that says we now have this available.

They've got a relational database. So if you said, "I like this kind of book," they'll send you an e-mail saying "Have you checked out this book?"

PC Flowers, which is terrific, has a service that's similar in the sense of — I think it's an anniversary reminder or it's a holiday reminder. So again, you give them kind of personal information about yourself, and in return they provide you with a service that is very, very valuable to you.

The other thing that is critical here is what they call the "Bill of Rights," and that is about privacy. They indicate right up-front, no-holds barred, "We're not doing anything with your name. That's our promise to you. Anything you tell us stays with us."

That, I think, is absolutely critical. There is no question that people today have enormous concerns about privacy, about whether information being given out on-line is moving around. We at *Pathfinder* promise we're not going to do anything with that information if you register.

When we started selling advertising, the first thing we said to advertisers is: "You can ask the consumer yourself. And if you set your site up correctly, the consumer will volunteer information to you."

But we promised that we will not pass any information about you. We — and I think everyone else in the industry, too — have held to that strongly. Because the need for privacy is a very, very strong feeling for consumers out there today.

All right. There are lots of activities that are here today that are forerunners of the future. All of it is just a glimpse of the customer service order-taking, the personalization that you can expect to see from marketers and marketing sites in the future.

Now, what else is going on? Well, as I think most of you know, the Web is getting crowded. Ten thousand new commercial domains are being established every month. It used to be that if you went up on the Web with a site, that in itself was news. People would check it out.

I was talking to a reporter who covers the on-line industry the other day. He said to me, "You know, I get about 40 calls a day from people who tell me they're putting up a Web site." I said, "Terrific. Send them to me."

But the point is that it's no longer news to put up a site. And it is no longer a guarantee that if you have a site, people will come to it. It's like having an 800 number that nobody necessarily will call. So, today — and an 800 number has no value if no one calls it — you increasingly see people who, as they're putting up their sites, are thinking, "Well, how do I also publicize my site? How do I build awareness? How do I get the word out?"

There are different ways of doing that. They range from hyperlink in high-traffic editorial sites — and that is essentially what is available in *Pathfinder* where you have lots of traffic moving through — and as I talked about before, [there are] non-intrusive invitations for consumers to go in and visit the site. Maybe today I wasn't thinking that I was going to investigate buying a new car, but I saw the icon and I thought, "this looks interesting. I'm thinking about in the future, at some point, I'm going to want to do this." So it's both awareness — I said, "Oh, they're there" — so now I know this marketer is on the Web. And it's certainly easy. With just a click, I can check out and see what they have to say.

[What's] another reason someone visit an advertiser's site? I get asked that a lot. Well, there are a couple of reasons. First, the Web is inherently a curious medium. People are here to explore. I do not think that as the Web becomes more of a mass place, that's going to go away. People have information needs. They want to buy things; they want to buy appropriate things. So they are both curious [about the Web and] they're interested in information.

Also, marketing has become a part of the experience. Marketers have begun to think about entertainment and creativity. How do I create value or a fun experience? And that's one of the challenges that right now marketers are facing. What is it? If I'm trying to sell something, everyone knows in the real world that [you need] a shopping environment that people like. A lot of people have theories. I want people to hang out. They hang out, they'll buy something.

The new Barnes & Noble stores in Manhattan have cafes and couches and chairs. They're built around the idea that if people come, and I set up a community, they'll hang out and ultimately they'll buy something. The trick, which everyone is facing now, is what is that in cyberspace? What is appropriate? How do I mix in some entertainment? Or, if I'm actually trying to create a transaction, what kind of mix of information, entertainment and product [should I use]? How do I display it? We'll talk about that in a second.

[Now let's look at] Web addresses in print ads. A year ago if you had put in a print ad "http," no one would have known what it was. Today, if you look at the Sunday movie ads, fully 50% of all movie ads are tagged with the URL, and it's becoming just like an 800 number. You're going to see it more and more. Basically marketers are saying, "Just like my 800 number, here's a place where you can go to get more information about my product."

It's a two-step kind of marketing. You see that kind of ad, it gets out the URL, and then you go into the Web for the detailed product information. And you're seeing that both in print and even on television. There are Web publicity campaigns. As you launch on the Web, you figure out what kind of sites are going to be interested in me, who's going to say, "Oh, this is now available!"

How do I let them know about myself? A couple of very quick examples. When one of our sister companies with Warner was launching *Batman Forever*, a month before the movie went out we put up a site. At the launch of the site, they took ads at the bottom of the *New York Times* where normally people kind of talk about anniversaries and other important events.

They said, to [inaudible] villains who plan on Gotham, <http://batmanforever.com>. We believe that was the first time a URL was on the front page of the *New York Times*. You went in, and what you found is tough to see here, but it was *Batman Forever* and Gotham City. As I think most of you know, *Batman Forever* had the most successful opening weekend of any movie in history. *USA Today*, in its reporting on that, said that one of the reasons was this site.

We talked about hyperlinks. At the bottom of *Pathfinder* [you see] "Prudential Securities," and "Win a Sable," and you see those are hyperlinked if the consumer is interested. If that kind of catches the consumer's attention, and they decide to accept that non-intrusive invitation, they click on.

Now, in this example, they've gone into Prudential's virtual branch office. One of the issues on the Web is that hyperlinks are a form of direct marketing. Increasingly, it kind of sweeps the industry. Marketers think about them as a form of direct marketing. [The idea is] to experiment in ad location, to experiment in creativity. And the idea is that pure corporate logos are likely to be less and less effective.

What you're trying to do is [think]: how do I get that consumer interested in going through the door, into what's behind the door? Well, you want to give the consumer a sense of what's behind the door. There's something exciting behind the door; there might be something different behind the door.

At Marketplace, MCI sponsors the *Interactor Daily*. At one point I noticed if you go there every day, they were starting to rotate their ads. And it's very clear they are rotating the creative [part] simply because there's obviously a belief that it's proving out. They're continuing it and that will lead to a higher yield. If people didn't respond to that creative, they'll respond to this creative, or maybe there's something different there. I have a very strong interest in saying, "We would love for you to rotate your ads, because we think it's going to increase your traffic."

When you evaluate your placement in *Pathfinder*, you're going to be much more of a satisfied customer. So, the interest of the people who are selling advertising — and the people who are buying it — are absolutely aligned in this case. I mean, you're going to see a lot of activity here in the next year.

[Here's] another: Say I Love You with Roses. An exciting thing.

I'm going to make a contrast here. Initial research that we've seen says that consumers who are on the Web do use it for product purchase decisions. Research that was done a couple of months ago said that for people buying things, they used the Web to get information about software or about hardware. Now, those were the areas of the Web where marketing is most developed, particularly several months ago. That was where there were the most sites. You would expect that to be the leading edge.

That, to us, was a validation of everything that I've just said. I want to contrast that with actual transactions. In our minds, there is a very significant difference between giving someone product information, helping them make a product decision, and the actual purchase on-line.

While 65% of people said they were using the Web for product information for software and hardware, only 15% said they actually bought on-line. And there's a whole variety of reasons why that is. Secure browsers have only recently become available. There's also a question about public perception of security. Not whether there is security, but does the public believe there's security?

Second, as I said, there hasn't been a lot to buy. Until recently, there have been few brand names on-line. The catalogs — and I think this is like the catalog boom — initially started because prices were more attractive. In the early 90s you bought by catalog because it was cheaper. Well, today it may be higher quality, or more convenient or a whole range of other things, but initially, to develop that channel marketers had compelling prices. Until recently, marketers on-line had not been giving consumers back the benefits of their lower costs through this channel. That's held it back.

Women do account for two-thirds of purchases in the United States, and there have been fewer women on-line. In general, it takes time for new habits to develop. It took some time for the ATM to catch on. I think one of the things I would say is that it's very unclear if the Internet is definitely established as a place for information and product purchases. It's an incredible place. I believe that ultimately transactions will explode, and ultimately, those transactions will be enormous.

But it may take some time. And I don't think we should think that in three months or in six months — of course in Internet terms that's six years — but we shouldn't necessarily believe that in three or six months you're going to see an enormous range of transactions. It may take a little while, because you are talking about establishing a fundamentally new consumer habit.

It does have the convenience. Like the ATM, people will figure out how to create a terrific environment for consumers to shop on-line. Like a real store, they'll see what works and what doesn't. And that's what marketers are struggling with. Ultimately, it is going to be enormous.

Okay. As I said, like the ATM, it will ultimately be enormous. All of the issues that are holding it back are going to disappear over time. You're going to have brand names; you're going to have secure browsers; you're going to have marketers who are experienced in how to interact with the consumer, which is what they're trying to figure out today.

In general, consumer use of the Web itself is going to grow. The timing is something I think no one knows. So, if I was going to wrap up, I would say that the Web is going to continue to evolve rapidly as a place for marketers.

It is becoming a mainstream medium, [both] for influencing product decisions and as a mechanism for low-cost communications with consumers. That includes order taking and customer service. "Let me tell you about an on-going relational discussion. Let me tell you about the latest products that might be of interest to you." Transactions are ultimately going to be enormous. Widespread purchases, as I said, may take some time.

That's all I have. That's as much as we've got time for. I'm open to questions.

M: [inaudible]

Bruce Judson: The question is, do we print the full text of the magazines? How much work is involved in moving from print to putting it on the Web? Typically, it depends on the publication as to what extent we publish the full publication or rely on selections. I don't have a simple answer there. The work is really putting it in HTML and then [deciding] how much design work you want to do. You can put a lot into creating terrific designs. or less work. It's really a site by site, publication by publication issue. Are there any other questions?

M: [inaudible]

Bruce Judson: A week. We've been very public about our advertising for 1995. We wanted it to be simple; it was \$30,000 for a quarter. And an advertiser rotates through *Pathfinder*. We think

that is about four million page views a week, which is kind of a currency of advertising. We are registering — but are not requiring authentication — every time someone comes in. So no, I cannot give you an estimate on the number of people. We've got some ideas, but we're going to wait until we really know to release those numbers.

M: [inaudible]

Bruce Judson: The question is about how the publisher makes money differently in this mode. We do not believe that there will be a tremendous difference. We believe we are putting tremendous resources into the creation of *Pathfinder*; the site itself changes every day. And it is a value issue. Consumers will pay for high quality, unbiased editorial. So there will be a dual revenue stream supported by consumer revenues, and by advertising revenues, just like a print version.

M: [inaudible]

Bruce Judson: As I said, it's a value issue. We believe that we are creating, and will create, products that the consumer [wants]. The consumer's going to decide. And the consumer is going to ask, "Have they done something that's so neat?" We believe we will create things that are valuable enough that consumers will say, "Yes, of course, I will pay for this. It's worth it. It's the kind of high quality thing that I want."

M: [inaudible]

Bruce Judson: Sure. The question is, what is MPA — Magazine Publishers' Association — talking about in terms of ad measurement? Have we seen any killer systems?

We have been talking today at more of a theoretical level. Two things. One is that if you operate a site, it's your responsibility to get it "counted." That may mean you have your own software, it may mean you use someone else's software.

But, which turns out to be the killer system? The thing that we have added is that we feel it is appropriate to have another layer which is an unbiased, third party — like an ABC or someone else — who is auditing those results. You're going to have a very competitive market for counting, so we want one auditing of what the sites are reporting.

Second, we would like to have, if nothing else, a common language. Today, you have hits, page views, quick streams, users, active users, registered users — and for most people there are probably five different definitions of each of those. For the whole ad industry to move forward we need a common language. What is a page view, what is a user, what is a visit?

M: [inaudible]

Bruce Judson: No. No. We would not use it without — sorry. We said we're not giving out information to advertisers that's individual, specific. The question is, are we going to use it ourselves? And the answer is no, with one exception. You may see from us, at some point, a question that says: "Would you be interested in offers that have this characteristic or that characteristic?" If you say yes, we will e-mail them to you. If you say no, you won't see anything. So, if we use them, they will all be used in response to your statement that you're interested in receiving information from us.

M: [inaudible]

Bruce Judson: Stay tuned. I'm sorry; the question was, have you thought about developing an electronic version of a reader response card where you can get information back from advertisers? I guess I would say the answer there, to that specific question, is no. If you're an advertiser in *Pathfinder* it means you basically have a Web site with in-depth information. Our notion of advertising is that we give someone the option of going there and visiting that site. But there are some related things that you may see in the service in a couple of months. There are some things like it that we are thinking about.

M: [inaudible]

Bruce Judson: The question is, what are the legal ramifications of putting other businesses names and addresses on your Home Page? And I guess I have to say that I don't know the answer to that. I'm being told the answer is "none." All I will say is that all of our advertisers, of course, sign a form saying, "We want this link, we are supplying you with this artwork," and that's the artwork that we are putting up.

M: [inaudible]

Bruce Judson: There is a defined schedule and you can also define the areas that you want to move. Oh, I'm sorry. The question was about rotation on *Pathfinder*. How do we define that rotation? And the answer is that as you sign up to be marketer on *Pathfinder*, we work with you to develop an appropriate rotation schedule because there may be certain sites that are likely to attract the type of demographics you want. So, you may want to rotate to certain areas and not other areas. And then you also get a certain rotation through a high-traffic area, like the Home Page and others.

M: [inaudible]

Bruce Judson: The statement is, I am one of those users who detests passwords and IDs and registration. So how are you going to control access? I think that is probably a short-term issue. In the near future your browser or whatever else you are using to go visit sites, will — if you have registered once — retain that information, or tell the site who you are. You yourself will not have to retype it in. I think that is a short-term issue that is going to be resolved by coming generations of technology that are not that far off.

M: [inaudible]

Bruce Judson: The question is about whether we're collecting demographics to identify prime times during the days, or weeks, for rotations on ads. I guess. We know when the service gets the most use.

All right. Thank you very much. I appreciate your time.

WORLDWIDE WEB
USING THE WORLDWIDE WEB FOR MARKETING:
THE SMALL BUSINESS PERSPECTIVE

MODERATOR

Ken Lane

WWW and On-line Information Consultant

SPEAKER

Jill Ellsworth, Ph.D.

Senior Partner, Oak Ridge Research

Ken Lane: I welcome you all. You look a little “conferenced-out” at this point in time, but thanks for coming. I’d like to give you a little bit of an idea of the format. We’ll have a presentation that will last about 40-45 minutes, or maybe a little longer, and you’ll have an opportunity for some questions and answers after the presentation. I also want to remind you that audio tapes will be available of not only this [presentation], but any other session that you might have missed; and there will be a CD-ROM available which will contain the entire proceedings of the conference. More information is available up by the registration area if you’re interested.

And now, ladies and gentlemen, it gives me great pleasure to introduce our next presenter. She’s a former university professor and dean, holds a Doctorate from Syracuse University, is a senior partner with Oakridge Research, is a consultant about business and marketing on the Internet for Fortune 500 companies and is a popular speaker in North America and Europe about business, marketing and education on the Internet.

She is the author of *The Internet Business Book*, *Marketing On The Internet* and *The Internet Business Kit*, which have been published by Wiley & Sons, and *Education On The Internet* and *The Internet Unleashed*. She serves on the Survey Working Group of the Internet Society and is an active, very active Internet participant.

Ladies and gentlemen, it gives me great pleasure to introduce Jill Ellsworth.

Jill Ellsworth: Boy, you hardly know what to say after something like that. Kind of scary.

What I want to talk about today is not only marketing on the Internet, but particularly the issues that hit small businesses as opposed to some of the big guys. They’re a little bit different and the solutions are a little bit different.

I just like this slide, so I put it up. It’s about the Internet. We talk about 30 to 50 million [Internet] users, but when we’re alone and talking to our colleagues we say, “We’re not too sure how many.” [With] 55,000 hosts worldwide and local networks hooking up to the Internet, the growth curves are amazing. I know all of you have seen those growth curves where it seems to go up to the sky, but in another life I was a statistics person and if you extrapolate all that, every person on the globe will be on the Internet in the year 2005. But we know that’s not true, so, so much for statistics.

I’ve been doing a lot of talking to businesses on-line, small and large, about what’s going on with that, what’s happening, how is it working? I’ve got one of those questions that I keep getting which is, “Is anyone making any money on the Internet?” You know, aside from people like me. And the answer is, “Yes.”

I’ve completed a research study with 460 businesses that are on-line, and I’ll tell you a little bit about that later. Then, after kind of gathering all of the general data, I talked to some people and this is one person that I spoke with — Faucets Online. Now, these folks sell really fascinating things — faucets and kitchen sinks and drains and shower heads and stuff — to other

businesses. They sell business-to-business pretty much, and for years they have had a really big catalog, pictures and pages that you turn, and then every time they changed the price they'd reprint this brochure and this catalog and it cost them a lot of money.

So they went onto the Internet to save some money, not so much to reach new customers; because, again, they're business-to-business, and if you want faucets they know you'll call them. But here's what Dan Sullivan said. He said, "We think we're able to show more of our products to the consumer than with any other medium. We're more on target with our market and we could show them more than they could find going to five or six different suppliers."

And they're thrilled not to be spending hundreds of thousands of dollars reprinting old brochures with one price change and then mailing those out.

So, Faucets is a good example of a business that is doing well with a Web page that's not all that snazzy. You know what I mean by snazzy Web pages? *Hot Wired*, [with their] pink colors, all those really great things. Well, that's not how the Faucets catalog is on-line. You find your product, you can move on down there and find it in chrome and brass and how much that's going to cost. It's really very plain and simple, but it serves their needs and their customers' needs.

Another person I talked to — and I get a lot of questions like this — people will say to me, "You know, are there any businesses that really shouldn't be on-line? Is it really wrong for some kind of business?" And the only answer I've had up until now was something like, "Well, my shade tree mechanic down the road from me probably doesn't need a Web page tomorrow; he may not even need e-mail at all." So, the answer has been something like this.

When I was doing my research it really surprised me to find Monty's Restaurant. Monty's is a small restaurant in Tempe, Arizona that has a Web page, and I'm thinking to myself, "Why do we need a Web page in Tempe, Arizona?" But, Monty says two things about the Internet. He says e-mail is the holy grail of customer service. He thinks it's absolutely terrific, and I'll tell you about how he uses UseNet groups here in a minute. Then he says his Web site offers the greatest marketing "bang for the buck" around anywhere these days. It's a little restaurant, and I said to myself, "I've got to talk to this guy. Let me find out what it is that he has to say about this, because it really surprised me." It turns out he does a couple of things.

He goes out on a UseNet group called "Phoenix Eats" where people talk about restaurants and local restaurants. He decided he better listen in on what his customers are saying, and so he now uses that as a way of finding out what's going on with his business and how it's going. And when he finds an unhappy customer, do you know what he does? He writes to them. He e-mails them and he says, "Listen, I know you had a bad time in my restaurant, I'd like to fix that, here's a coupon, bring your family and eat on us." But, he actually does find out what's wrong and what's going on.

And I said to him, "But still, what about this Web page?" He said, "Well, we're fairly wired in town and people use it to find my menus. They "clip" my coupons and they come in." He said, "I've been asking people if they're really using my Web page, and they are."

So, my assessment — that local business drawing local business may not need a Web page — I may have to think about. But I still don't think my mechanic needs to go on-line, either. That's my hunch. Here's Monty's down in the corner there. He has his restaurant in an old house, an old house that he's remodeled. But again, it's not a jazzy Web page, but you can clip the coupon. It didn't do me any good, I live in Texas.

SDG Insurance says after only five weeks that their Web site has paid for itself, and it's been the best advertising they have ever done. And then they compare it to a direct mail piece that they mail out, and what kind of return they're getting on that — 3%. Then they compare

that with their Web page, and they're getting a 10-12% return rate. I was kind of surprised about that.

I decided — with Jim, as well — to find out how things were going, and he said he really likes being on the Web because he finds that he gets more kinds of customers. He uses a data input form that he's able to then respond to, and he's getting a real good return. He's feeling real good about his investment and how that's working for him. He also uses e-mail — no surprise — to be in touch with his customers. And again, it's not a real jazzy page. It's very plain and simple; you do your data input, he turns it around and gets back to you. It's not anything fancy, it's not *Hot Wired* or hot colors or anything like that. He's certainly not using *Java* yet.

Well, let's talk for a second about how big the Internet is for the moment — because that's the only way we know how to look at it is by the moment, it changes so quickly. A couple of things I want you to think about, especially for small business, is that small businesses are finding that e-mail is very effective and that's very much in line with the demographics that we have.

The full access folks — those are the folks with the Web pages, the full Web access and so forth — this number is growing due to a lot of the on-line services, etc.

Then there's a middle group, who might have some of the other food groups of the Internet.

And then the largest group with e-mail. Small businesses tend to deal with other small businesses or individuals, and they find that this e-mail angle is extremely important to them.

Commercial domains are still growing. We don't know how much longer that's going to happen, but it's still happening. The commercial domain is huge. The WorldWide Web is growing and people say a hundred million by 1998. But remember, marketers, that they can't all see your Web page, and they can't all FTP and they can't all Gopher, but many of them can e-mail and one of the strengths for a small business is that e-mail contact, that getting close to the customer.

Who is out there? I was doing a speech at a conference yesterday where some of the CommerceNet information was being explained and talked about. There must be now, ten or fifteen or twenty on-line sources of information about who is on the Internet and on-line demographics.

At this point, I think the best thing to do is to look at them all, think about them all, and to ask yourself if you're a small business person, "Are my customers on-line, or are they likely to be in the next 12 months?" The problem is that I'll see a business that wants to go on-line because it's the neat thing to do; and it is, but I say, "Well, are your customers there, do you think, or will they be anytime soon?" And the answer is, "No, they're not there yet and no, they're not ever probably going to be there." Then I said, "Well, then a Web page is sort of like your own personal entertainment. It's not really going to help you with this marketing issue."

[There are] lots of issues around validity and reliability, as statisticians talk a lot about that stuff. But, what it means is that you should be cautious with any one survey. I'm not tarring and feathering them all; but it may not apply to another site or to you, it may apply to only the site where they took the statistics.

[There is] lots of talk about how many men and women are on-line. The information recently seems to be perhaps one-third women, two-thirds men. So if you're marketing to women, especially as a small business, you may need to go to some extra lengths in order to reach them.

Regarding age ranges, we have some in their early 20's and some in their mid 30's to 40's. Again, if you're going to be a small business marketing to folks in their 70's, they may not be on the Web yet for you. Although my dad is, so watch that.

The occupations, again, tend to be white collar, computer academic and so forth.

Income tends to have two humps, one we think for the new graduate from school who has had those [Internet access] tools and thinks of them as theirs, and second the sort of middle managers in their middle 40's, highly educated. Their Web tools have us look at the Web a little differently. Again though, perhaps one-third women, perhaps two-thirds men.

The average age seems to be around 35. Again, mostly in the technical fields and education.

I want to talk for a minute about a figure that I saw running around about average income on the Web as [being] \$69,000. As a person who does statistics you know there's facts and statistics and all that, and all those scientific ways of looking at numbers and looking at data. But this one I look at with my heart or my gut and I say, "I don't think that one's right. I haven't got any scientific proof, but I don't think it's right." I do not think the average income is as high as \$69,000. I think it's more like the \$35,000 to \$40,000 that we see. This all has implications for all marketers, but particularly for small businesses who almost always are hunting for a little bit narrower group.

So, why is a business interested in being on the Internet at all? Lots of reasons: communication, internal and external, corporate logistics sometimes, or even internal Web pages for the development of, say, personnel manuals and so forth.

The whole issue of globalization, reaching beyond your city, or your state or your country, or North America — those lines get very blurred on the Internet, and small businesses particularly have to be careful of that. If they're not prepared to fulfill orders, say for example in Canada or Mexico, or in Europe or in Asia, they can get into some trouble on the Internet by advertising that they have this stuff [for which] they can't fulfill orders. That's true of large businesses as well, but large businesses tend to have the resources to fix problems rather quickly, or have already solved that.

This next one is the place where you see, I think, the most value for small businesses being on the Internet and on the Web. It is the leveling of the playing field. You do see a lot of businesses on-line that are run from the back bedroom or from the basement office, or two people or three people or four people working together. If you do a real good job on the Internet and on the Web, they don't know that you're operating from your basement as opposed to the Trump Towers. That's one of those really competitive advantage things that comes through for the small business person.

Cost-containment is another area. Collaboration and development is very important for small business. Small businesses need to think about, instead of just a competitor, think of that competitor as a possible collaborator on a project that your business is too small to get; but together you can form a dynamite team for getting that bid or getting that business. Small business is very much making use of that.

Obviously, on the Internet there's tons of information, the whole drinking from the fire hose and just overwhelming kinds of things. And, of course, marketing and sales is one of the most obvious areas.

The globalization, the leveling of the playing field area is, as I said, one of the places that I think small businesses could make the most hay while the sun shines. They need to remember that it is international, that it crosses time zones and boundaries and so forth, and on the Internet you can gain some equality. I don't think you can gain perfect equality on the Internet; Microsoft and Bill Gates are still going to have a lot more money than you have, and can do more things than you can, but you could compete on certain things.

Marketing, sales and PR — this is one the areas where small businesses are really, really making a dent in their competitors and are able to compete very well. I call it "marketing through content," not marketing through empty messages. We do it for all the same reasons: the advertising, visibility, brand name recognition, all those things, the whole creation of a

business presence is there in the marketing and sales. You can do marketing research, and you could find out what your competitor is up to in some instances, especially if you hang out on certain lists. You'd be surprised what people will tell you on those lists.

We hit direct sales malls and on-line ordering. I'll give you my own personal assessment about malls; horizontal malls try to emulate a shopping mall. They don't seem to be doing very well for the small businesses — or for anybody else, for that matter. I don't know about you, but the reason I go to the mall is that sure, I go to shop and to watch people, catch something to eat, maybe a movie; and that's hard to do on-line. The vertical malls, where we have information and products all in one area, in one business, seem to do a great deal better.

On-line ordering is getting easier. You can put out product information, you can do customer service. One of the real strengths of the Internet is customer service, technical assistance of all kinds, public relations and community service. I want to remind you, as all kinds of business owners on the Internet, that you need to remember to give back to the Internet something interesting.

This is an issue I stress probably in every speech that I give, which is that when you want to do business on the Internet you need to become part of that culture. It's the issue of "When in Rome, do as Romans do." If you're trying to sell, literally, products in Italy, you must sell them in a way that makes sense to Italian consumers; and on the Internet you must sell these products or do this business in a way that makes sense to the folks on the Internet.

It's not so much a legal issue as a cultural issue, the issue of "in-your-face" advertising versus "marketing through content," and the issues surrounding spamming. We're getting a lot of that right now. I don't know about you, but I am.

When we talk about marketing engagement on a Web page, we want to talk about what's going to get people there to visit. We're going to give them something to do, some activities. We're going to do something useful. One of the slides I use to have here but don't today is FedEx. They've made [their Web site] useful, they've turned me into a customer.

There's the interactivity of contests, surveys, and becoming a member. Increasingly you're seeing Web pages that stress that the customer can give you some information and at the same time you can make them feel part of what you're doing. The marketing and information and the issues around content — it's an old saying, but with real estate you have the "location, location, location," and on the Internet it's at least "content, content, content." But increasingly it's interactivity and usefulness as well.

One of the pieces of research that I've been doing is looking at who're making money, and that's going to help you make for a success. And one of the things I set out to do is to interview some people whose on-line business did not do so well; you know, what we might call business failures on the Internet, or "road kill on the [Information] Super Highway."

One of the biggest things that I found was that these folks had a great idea, they had a really interesting idea for business — and had no sense about business. They did not know how to do business and so off-line or on-line, they would have not made it. They thought that by putting up a really snappy Web page they could kick back, put their feet up and wait for the customers and the money to roll in. It just doesn't work that way.

Of course, one of the big keys is getting your page registered out there on *Lycos* and *WebCrawler* and *Excite* and *InfoSeek* and *McKinley* and all those search engines, getting out on the discussion lists and using your SIG file and all those things. It's just really important, because I looked at a couple of business failures and I said to them, "Well, your page looks really interesting, how much business did you get off of it?" [They answered,] "Basically, none." So I said, "Well let me check that out." And I kind of checked through all the basic search engines to try to find them and I couldn't. So if I couldn't find them, and I'm pretty good at ferreting that

stuff out, think about your average consumer trying to do that. So some of these failures have had a lot to do with visibility.

[I've been] mentioning the search engines and so forth by name; there's lots more than this and there's more coming. Remember *Trade Wave Galaxy*, that use to be *El Net Galaxy*? Now it's *Trade Wave*, [*Witcern Commercial Sites Index*] and all that. Don't forget, if you have a Gopher, to have it registered with *Veronica*. I'm going to make a note on Gopher here in a second via FTP and the old, you know, "you help [me] and I'll help you."

One of the things that I discovered in doing some of this research about who's succeeding on-line and what's going on on-line with business is — and I don't think it's any surprise to most of you — that Gopher sites are going away. They're becoming a little bit dead. There are fewer of them that are really good than there used to be. I'm not ringing the death bell on Gopher, I'm just saying be aware that it's not what it maybe used to be.

FTP still seems to be hanging in there as a support particularly for companies that deliver information or software. It's a great way to do it and that's still strong, although I'm seeing a lot fewer text and information files on FTP. So that's kind of going on.

I encourage everyone to promote their Web sites with other media. I don't know about you, but I'm seeing a lot more URLs on TV. I'm seeing a lot more URLs on signs outside of businesses and I'm seeing a lot more of them on business cards.

I live near Austin, Texas and was zooming through town and the big entertainment center said, "Check out what's coming — [http...](http://...)" and I went, "Whoa, cool, very nice." And I zoomed off of the highway to go to the airport and saw Southwest Airlines, check it out, Harley Davidson, all of those things. You're seeing URLs in places that you never did before.

On CBS News, the day before yesterday, [there was] a big vote in Canada about whether Quebec was going to leave Canada or not, and I was interested in that. So, I'm checking this Web page all day. First of all, the "Yes" votes were winning and then things caught up and finally the "No" for splitting up won the vote. But, increasingly we're looking for that kind of information. Seeing your Web site out there providing some of that sort of information is real important. Don't think about URLs on radio too much, though. They don't work too well.

So, in doing this research, let me just summarize some of the things that I've found particularly for small businesses. Now, a lot of this works for big business too, but not every bit of it.

I say there are no invisible Web sites, so be sure you're registered. There are no dead Webs. You've seen them, you know who they are. You go out there and the site looks like no one's been there in a very long time, it's a ghost town.

New pages [should be] added, old pages updated and given face-lifts. Successful pages are information rich, with good content, often what I call "more than a visitor can absorb in one visit," because it gives them a reason to come back. Don't lose them, but do that.

They have clear navigation. Users can move through the site easily, arrows or icons are clear. Moving around seems intuitive; it seems the way you want to work it.

The next point is one that I can't see because of the lights, but I'm guessing that there are folks here from *I-Net Marketing*, and we've talked about this one on *I-Net Marketing*. Their pages do not funnel the user out too quickly. Do not send them away right away. I mean, it's like a story. You've got them in the door, do you want them leaving right then? I don't think so.

Make sure your links [going] out make sense. Do they add something to your site to have them out and try to bring them back? I've seen some very, very unsuccessful pages where the very first thing they do is, "Ta da, we're here." You know, they've worked hard to get your feet in the door and then they immediately send you away. I don't think that's the right thing to do. I'm for modest use of links out, and I think it's real important that you take care of that.

[Also, make sure that] the site has true added value. Now, this relates, in a certain sense, to my previous point. The previous point was: don't link out too much. Well, added value is not a whole bunch of links out. You'd be surprised how many people are doing it. It's real services, it's real content, it's real products or other resources. A site is not just a place to market and sell; it's a place to provide information, stuff for free and so forth.

Again, this is a part of this issue of, "When in Rome, do as the Romans do." Folks on the Internet expect to get some stuff for free. They're accustomed to that. They don't mind if you try to sell them something, but give them something, too. Give them some information, help them out. So, successful sites are not just for sales, they're for other reasons.

[Be sure that your] site maintainers are responsive so that you don't click there and find that dreaded "404 — URL not found." I don't like that either.

[Be sure] the site has organizational or institutional support, and is not run by the guys out back — it has a budget, it has all kinds of stuff. It's not dependent, like Blanche Dubois, "on the generosity of others." It has its own budget and has those kinds of things.

[Make sure] the site is capable of gathering information, and you can get stuff about your users. I'm not just talking about your logs, your logging and the site tracking stuff; I'm talking about getting people involved through newsletters, surveys, stuff like this, so you know who's been visiting there, their preferences and reactions. I saw a TV show last night, Nightline, about all the information that's being gathered on consumers; and I assure you it's going on on Web pages. But where you do know people's preferences and what they want, let's make use of that.

[I want] to reiterate a couple of things, like [using the Web as a] marketing channel with other channels. It's supported with other Internet tools; you have your e-mail set up and so forth, your bots and so forth, your automatic mail-out.

[Make sure] the site has good design. And there are just a few things that make for some rules of good design, which are no way meant to say you shouldn't do creative things; but make sure that you have alternatives for those really large IS maps, the ones that I call the "laundry IS maps." I can do my laundry while I wait on them.

Interactivity with real people is available. I was at a site the other day and I kept clicking and clicking and clicking to find someone to give some feedback to — forget it. It didn't work.

[Make sure] the site is sensible versus hot and that the graphics, design and colors are in sync with the corporate image. You know, *Hot Wired* is in sync with their corporate image; but if you have a site like hot-wired for 3M or Rolls Royce of Beverly Hills, I don't think so. It needs to make sense. It needs to make sense with your other imaging that you do on TV or in your other things.

[Make sure] that the site has some consistent imagery and content from page to page, so I don't feel like I've left your site all of a sudden because I don't understand the images that I'm getting.

[Make sure] the URL isn't funny-looking with the tildes and stuff. This is increasingly important for businesses — that I know their name. I was looking for a business the other day, a small business, and I hunted through *Yahoo* and didn't find them. I hunted and hunted and finally said, "well let me try "www.com" and so forth, and sure enough I found them. That was a good deal and I think that's important.

How does the little guy keep ahead using the Internet? Well, I say, "use the Internet." There are some issues that arose out of the research that I was doing for what made it so that the little guy, the small business, could get ahead. Here's what I found out from that.

They need to do what's called "helicoptering." Get above the fray and have a look at the big picture, see what's going on, scope it out. They need a headlight to look beyond the horizon and see what's over the next hill and around the next corner. The little guy needs, probably more than the big guy, to do their homework. Know the competition. Scope out what they're

up to. Form alliances. Again, as I said, if you think that you have a strength and your competitor has a strength, together you might be able to go after bigger jobs. Don't always think of it as a competitor. And you might not join up forever; you might only join for a while.

Make your site more dynamic or more creative. As I say at the bottom, you can't outspend them, but you can outsmart them, outfox them, and outmaneuver them. I mean, as I say, Bill Gates is — you know, the lint in his pocket is worth more than all the small businesses put together. You can't outspend Microsoft, but you might be able to be fast-twitch, nimble, what I call "ducking and running."

What many people use to be a small business — it's getting bigger. At Netscape, that's what they're good at. They have outmaneuvered, they have ducked, they have run, they have headlighted, they have done all of these things and they're about to make money, I think. Their initial public offering certainly went well for some of this. I was a stockholder for a little while; but I heard recently that they're about to do a dividend of about 4 cents a share. Well, they're making money, finally. They've been through an acquisition mode and now they're doing that. So think about those issues.

Well, we've got lots of "opportunities" regarding business on the Internet; that's what we say when we really mean trouble, or we like to call those "challenges." It's opportunities for problems as well. Here's where I think that there are opportunities for new businesses, and what on-line businesses need to think about right now.

Security data authentication transactions. [There are a] lot of folks hard at work on that. I think that for the most part we're about to solve the public's perception about some of the problems.

We are seeing an increasing number of what are called "spams" or "commercial e-mail" that is unsolicited, and I think we need to work on some ways to help the e-mail box holder solve some of that. We're seeing some changes in Internet culture from what we use to think of as the cooperative Internet. I was talking with a friend of mine, another Net old-timer, and we think that a lot of Net old-timers are engaging in rose-colored glasses. It was never that great. I can sure remember getting myself burned pretty good on-line.

But things are changing a bit, so let's look at that — figuring out who's on-line, who's our market, the demographics. I think we're beginning to solve some of that. The whole future is sponsorships and advertising. Will we have HTML tags that allow one at the top of a page? Will we figure out — and I think we will — how to change the ad depending on who's hitting the page and what their interests are? I think we're going to do that with the issues around "searchbots" and intelligent agents of all sorts.

There's the shopping agent, the information agent, and all of the things we want to do with bandwidths. I want *InternetPhone*, and I want it now. I want full motion video, and I want it now. We're going to have to solve some of those.

Who's in charge of the Internet? Nobody, but some folks would like to be. What we're doing with HTML, SGML, *Blackbird*, *Netscape*, all of those kinds of things, I call it "Clash of the Titans," although I don't think that Bill Gates would appreciate me equating Netscape with what he's up to.

What do we do about the bad parts of town? There are bad parts of town on the Internet and we need to think about ways of handling that without saying, "Let's shut it all down." I have a little bit of information, if I can find my sheet.

I just finished a study of information on who's making business on the Internet. I asked 400-something businesses that question, and 82% of them said they were making money. Now, I went into more detail than that, but I did want to know that from them. I asked them how many were satisfied with their return on their investment, and 70% of them were happy with that. Now, by return in investment they meant some things like growth and profitability,

obviously; but with especially small businesses, when they're growing they're rolling back their profits into the business so the bottom line may not look as good as the fact that their business has doubled.

I asked about how long it was taking for Web sites to return on their investment, and the average is around six months. That surprised me; I thought it would be a whole lot longer than that. In some cases it was as short as half a month and in some cases long as, they figure, 24 months.

I asked them how they figured that return on investment. They told me that [they figured it in] overall business growth and profitability. And if it was sales, they actually did a return on their investment based on dollar figures, customer responses and some of their site-logging data.

A lot of businesses on the Internet are small businesses, and 41% of the ones that I surveyed had one to ten employees, and a lot of them had these single guy employees — you know, the one guy who's there. Although, interestingly enough, where it was a very tiny business — the Federal Government says a small business is less than 500,000 employees or something. I'm always amazed at that.

But when we talked about the size of the business being from one to ten employees, about half and half were men and women. That really surprised me. I was amazed at that. Of course, as soon as we move up from there those percentages change radically to where, if the business has more than 500 employees, there were no women who were the head of the business. The rest were men.

I asked them about elements of success, and I had some of that at this presentation. The biggest element for success for these folks was internal support and actual allocation of budget and personnel. I think that's real clear from that.

I asked them to do a prediction. Now, they're on the Internet — these are businesses on the Internet, currently doing some sort of business, apparently successfully. I asked them how important it was for other businesses to be on the Internet, and 9% said it was of the highest importance, 24% said very important, and 38% said important. The rest of them said, "It's a dog, leave it alone." But, I was fairly surprised at that.

I have more data to crunch — that's what statisticians say they do with data, is they crunch it.

What I'd like to do now is to take questions. What I'll need is for people to be fairly loud with what they say, because again the lights make it so that I can't see anybody in the audience, so I won't be able to help call on people very well. Do people have questions that they want to ask?

Yes, go ahead.

M: Per your surveys, what percentage of the businesses are actually selling on the Internet as opposed to a catalog?

Jill Ellsworth: The question was, "Of the people that I surveyed, what percentage were selling from their Page or using the Internet to do business, to do marketing, and to do all that visibility stuff?" And it was about one-thirds selling, about two-thirds not selling of the ones that I surveyed, and I tried very hard to keep track of making the survey look like the rest of the Net. So, that was about where it was.

[Tape change]

M: [inaudible]

Jill Ellsworth: Okay, I do, actually. The question had to do with those that were successful, that were doing selling versus — I'll call it marketing. Let me look here. The levels of satisfaction were — for marketing, those using a page only for marketing, not to sell stuff — went something like this: completely satisfied, 16%. Very satisfied, 27%. Satisfied, 28%. Unsatisfied, 18%.

Those doing sales, they were skewed slightly less toward satisfaction with 14% completely satisfied, only 22% very satisfied and 31% satisfied. So, it was just downwards toward general satisfaction, as opposed to the higher levels. I think that has a lot to do with fulfilling the goals that you set out to do for the Page. If you're only marketing and doing branding, I think you're a little bit more likely to be satisfied than if you're actually selling goods, so that, "I sold 12 widgets and I'm not satisfied," or "I sold 12 widgets and I am satisfied." I think that's what it had to do with.

Other questions? Yes. Down here in front, the only person I could see.

M: How many companies go from inside to out?

Jill Ellsworth: The question was, how many of these companies develop their Pages inside, or outside? I have some data on that, but I'm not finished looking at it. I eyeballed it and it seems to me that the satisfaction came mostly for the people who put their Page on someone else's server and had some help setting it up. I've not got complete data on that. My anecdotal data tells me that's true.

There's a small percentage who created this all themselves and are quite satisfied because they only invested like \$200 or something, so they're going, "Yeah, cool." I think those are the people with half a month return on their investment on their Web site, but I'm not finished with that data yet. I wish I had it in a form that made sense, but I just haven't had a chance to finish it.

Yes.

M: How would 462 sites select [inaudible].

Jill Ellsworth: I'll rephrase that and see if I answer your question. He wants to know where I found the 462 businesses. For the last couple of years I've been trying to keep track of sizes and kinds of businesses on the Internet [that are] using it. I tried to randomize that in what's called in statistics, "stratified randomness," to meet those size criteria.

I actually sent surveys to around 510 business, but as usual there are some folks who told me to mind my own business and leave them alone — and then there were some folks who were trying to be incredibly helpful by not answering the question that I asked with the numbers and giving me a full-blown answer to that question.

So some of those I had to leave out, but I tried to achieve some randomness across sizes as I'd seen it develop across the last couple of years. I would be the first to say that one of the things you have to keep in mind is that it's a snapshot. It was done across the summer. It's no longer exactly accurate because things have changed.

Did you have a question?

M: [inaudible]

Jill Ellsworth: Oh, okay. Most of the search engines that I'm familiar with do one of two things: they either take on all comers — in other words, if you want to register your page at, say,

Yahoo, there's a data entry page and you put it in and in general, unless there's something wrong with it, they list it. Then some of them — my memory is on *McKinley*, I don't remember about *Excite*, but I do remember *McKinley* — they agree to rate your site and if it's okay they'll give it a rating and put it in their database. But, they're not charging you for that.

Go ahead.

M: Isn't there a way also that we can [inaudible].

Jill Ellsworth: Yes, and let me use *Yahoo* as an example. Let's suppose that you're selling faucets like our friends that were selling faucets; they're going to want to link under a couple of different areas like hardware, or bathrooms, or kitchens and so forth. And that's why doing the registrations yourself [is a good idea], instead of through one of these big, big *Submit It* sites.

I love *Submit It*, and I've used it, but my sense is you get a lot more accurate submission to a search engine by doing that by hand — that is to say doing them individually and doing them under the right categories. You know, as I say, faucets should have been under faucets and hardware and sinks and tubs and whatever else was available to them. And different sites will have different of those categories.

Other questions? Can't see you. Yes.

M: [inaudible]

Jill Ellsworth: I'm sorry, I couldn't hear you. Could you speak a little louder?

M: [inaudible]

Jill Ellsworth: Oh, in terms of security? I haven't dealt with that a lot, but most people tended to believe, most business tended to believe, that if they were careful they could maintain site security through firewalls and other things; but customer's perceptions were that it was less secure than it was. And I'm not surprised about that.

I remember when credit cards — you know, people tell me about when credit cards came out, that people were nervous about using them. And I remember being a little nervous about using an 800-number and giving my credit card number to that person, but I got over that real quick. I now do that a lot, and I also shop on-line and I occasionally send my credit card in e-mail. I know that there are those of you who are cringing in your seat when I say that.

Other questions that I can answer? Yes.

M: [inaudible]

Jill Ellsworth: I was offered \$8,000 for it at a conference yesterday and I just don't think that's the right thing to do. I'm not done crunching the data, which is why it wasn't in my presentation, but I had some of it and wanted to give that to people. My sense is that what I'll probably do is to put most of it up on my Web Page and will, most likely, share some of the rest of it with my consulting clients, but I don't intend to package it and sell it for \$500 a pop. I'm a Net old-timer, and that doesn't feel quite right at this point. So, you could look for some results shortly on my Web Page.

M: Do you do other types, or is that what you do, you generally research?

Jill Ellsworth: I do mostly marketing research, and in this particular case it was simply that I was, to put it bluntly, “pissed off” with hearing about over here the people who said, “You know what, no one is making money on the Internet.” And I thought, “Well, that doesn’t sound right to me.” And then I overheard people saying, “You know, everybody is making money on the Internet.” And I thought, “Well you know that doesn’t sound like it’s right either.” That’s certainly not the people I know.

I felt that it was someplace in between, and I felt as if, given my background, that’s something I could help to find out.

I certainly don’t think that my studies are the be-all and end-all; I think it’s the start that had maybe helped some bigger organizations get started on looking at this. We’ve done that with demographics, where we’ve gotten a lot of people interested, and I think that’s been very positive for marketing on the Internet.

I think this is a start at looking at the businesses instead of the users, the customers. Now, let’s have a look at the businesses — here some folks are making money. Some folks are making big money. Some folks are not making big money, but feeling okay about that.

Other questions? Yes.

M: Is there a way to find out how many people are on the Internet in terms of certain geographical areas?

Jill Ellsworth: No. The question was, is there a way to find out how many people are on the Internet by geographic area or in a certain geographic area? And the answer is, no. I think there are ways to estimate it, but not with a great deal of precision.

Now, let me tell you why I think that’s so. I’m “Our Lady of Perpetual Surfing,” and I have lots of Internet accounts. When people count, they count me lots of times; or my sister-in-law has an account with AOL, and she and her whole family are on and they think that’s one. Those are very difficult things to average out.

I would say the best data on that is from [John Quartermen] of Matrix Information Services, www.mids.org, and the Internet Society, that is isoc.org. I would look for that, but no, you’re not going to find out exact numbers. You’re going to find estimates and extrapolations.

Other questions? Yes.

W: [inaudible]

Jill Ellsworth: I can’t hear you at all. Come up and talk to me and then I’ll tell them. How’s that?

W: What’s the biggest mistake small businesses make when they go on-line?

Jill Ellsworth: Her question is, “What is the biggest mistake that small businesses make when they go on-line?” I would say that there are two mistakes that come right to the top. The first one is they put together a Web Page that’s got lots of blinking and flashing and funny background paper and all this, and you can’t read it. They have the classic blue-on-black letters. They don’t know how to do that. So that’s a mistake.

But more importantly, when they go on-line they have unrealistic expectations for what’s going to happen to them and fail to register, fail to make themselves visible.

Then, I guess third of all, there are businesses where their customers are not on-line and not likely to be, and a Web Page doesn’t make a lot of sense. So that’s three. I mean she asked for one, but you know, give her three.

Could I help someone else? Yes.

M: What's your all-time favorite site?

Jill Ellsworth: Oh boy, you really know how to hurt a person. Well, I've got several favorites and they come and go depending on what I'm up to. I have to say that FedEx is a favorite of mine. I'm a "Type A" person and I love to track my packages. I want to know exactly where they are and that Page works like a son-of-a-gun. I love it. So, that's a favorite.

Another favorite of mine is a new favorite, so you see they come and go. It is the amazon.com books site. I recently went and bought a lot of books from them, and one of the reasons I did is they have unusual books. I bought a Herman Hesse book, *The Glass Bead Game*, that I've been hunting for — and you're thinking, "boy, there's a yawn." It's a book I was hunting for and they had it and I pressed it and got it. So, what favorite is changes according to what I'm doing.

When I'm doing a lot of research and hunting, Lycos is a favorite of mine, www.lycos.com; I love it as a search engine. But I guess FedEx has an effective page. Hewlett-Packard is certainly an effective page for getting information, for figuring out stuff. So, that's more than one.

Anything else I can help you with? Yes.

M: [inaudible]

Jill Ellsworth: No, you won't. You know the story about the cobbler's children having no shoes? My Page needs updating, and it hasn't been in a while, so I have not maintained fresh content. I've violated one of my own rules. You'll find it okay, but you won't find it great. Please, don't send me mail about that.

Anyone else?

M: How fresh is fresh?

Jill Ellsworth: How fresh is fresh? Well, that's a good question. His question is, how fresh is fresh? It seems to me that the answer is different depending on the purpose of your site. Let's take Hewlett-Packard. Fresh at Hewlett-Packard means that the parts are up-to-date, the prices are up-to-date and the information is accurate. Now, is that a week old or is it a month old? I don't think that matters; I think it's fresh in that it is completely accurate.

Where you're trying to generate a lot of foot traffic and do a lot of interesting things, then be flashy on the Net. I mean, it could be hours of fresh, you know. And if you're a news site, fresh means right now.

So it matters a lot what your business is. And in my case, I think I'm only slightly out of fresh, but I'm out of fresh, yeah.

Go ahead.

M: [inaudible]

Jill Ellsworth: I'll paraphrase the question and see if I can answer it. The question, I think, is, "How important is it for a page to have an on-line transaction form to do it right there or to have alternative ways of purchasing stuff, say through an 800 [number] or through e-mail?" Is that it?

M: No. For example, [inaudible].

Jill Ellsworth: Okay. It seems to me that the key to success with being able to sell off of a Page has to do with, and I know this sounds funny, the degree to which the sale is an impulse sale.

A site that's appealing, with small amounts of money — to impulse sales right there I think it's very important to have e-cash or some mechanism or a form, really quickly, to do that. And if it's a small amount, let's say \$20 or less, I think it doesn't matter to the consumer.

Now, when I'm beginning to spend more money, say \$500 for some really great software package, I think it matters a lot more to me how secure that is and the way in which it's done. And my hunch is, I may be wrong, but a \$500 purchase is less of a pleasure purchase or less of an impulse purchase. So, I think it has to do with the size of the purchase and the relative impulsivity of that. That's my hunch about that.

Yes.

M: [inaudible]

Jill Ellsworth: Oh, of those sites that I studied out of the U.S. — there were 42 that were outside of the U.S. and I did not screen for that. I say they own the Net. The vast majority of those were in Canada, but again that represents the fact that Canada is really on the Net, you know, and in some ways really more wired than we are.

Other questions? Yes.

M: [inaudible]

Jill Ellsworth: Not yet. I'm hoping to get it there. What I'll probably do is put a *PowerPoint* file there, and I'll try to include some of the statistics.

I think I'm out of time, but I can take one more? No? I guess we are out of time. Thanks very much. I appreciate your attendance.

[Two speakers were removed from this transcript at their request.]

Jane Dysart: Good morning. This is the beginning of [the] Hot New Technology track. The first session is going to focus on new technology and new products that have appeared at the show. My name is Jane Dysart, and I'm the moderator this morning. I'm the principal partner of Dysart and Jones Associates, an Information Management Consulting Company in Toronto and I also handle the program for Internet World, Canada for Mecklermedia and participate in some of their other shows.

With me up here are Hope Tillman, who is hiding back there, and Walt Howe. Hope is Director of Libraries at Boston College, and Walt is the InternetSIG Manager for Delphi Internet Services Corp. They are both net writers and in fact they met and married, not via the Internet to get married, but did meet that way. So they have gone with me through the exhibit hall and attended some press conferences because I'm sure, you have all have found over the last couple of days, it's quite mind boggling trying to sort through all of the things that are being presented at this show with the hundreds of exhibits and hundreds of products, it's really difficult to determine what's important, what's going to the be future, what we're going to look at down the road, etc.

Things are just changing and so fast and what we're trying to do this morning, or what we will try to do this morning, is to focus on some of the trends. They are not the only ways, they are the ones that we have selected to show to you this morning. Some of them include some significant new products or products that were not on the Internet landscape six months ago. We want to highlight some examples and want to apologize for any we may have overlooked, but as you can see that hall is very large and the number of companies so huge that

it's difficult to sort through. Definitely a challenge and hopefully at the end we'll have a bit of time for you to tell us some of the things that we may not have highlighted but that you think are some of the trends that the future or the hot new technologies or products that are coming along.

Certainly, there are lots of Internet providers and Internet access services out there on the floor as well as a lot of hardware and software suppliers. The program this time [inaudible] sorted in the pack by general categories, some of the exhibitions each [inaudible] if you try to focus in on ways. Our focus today has been influenced by the first keynote speaker, Eric Schmidt from Sun Microsystems, because he said content is king, so for this session what we have done is sort of loosely base our program around content.

We're going to start off looking at security and enabling commerce facilitating commerce to happen over the Net. We'll look at tracking, look at who's doing what on the Net, measuring what's happening, what's going on out there as well as how to track the delivery of content so that you ensure payment or you could focus on copyright and intellectual property.

We'll move onto filtering, obviously, something that is key with the volume of mail, products, and technology that's out there. So with our filtering — we'll start first with filtering, e-mail from various sources that [inaudible] a real challenge to keep us. We'll look at filtering content. How to focus on what's really important to you. And then we'll look at filtering for child protection.

We'll have, at that point, a short break and then we'll move to look at some of the new trends and things that are happening with browsers and views of the content. A little bit about authoring tools and the way we add content to the Net.

In some of the sessions later this afternoon the focus will be on other aspects of content — sound, video, gaming — those kinds of things, so the format and what we want to pilot today is to have some short presentations from a few of the companies that we selected. I want to thank them in advance for taking the time out of the exhibit hall. It's very busy out there and they have lots of people here but still not enough to meet the demand for information, so we really appreciate their taking the time to come today and tell us about their products.

So we'll take some short presentation, then we'll take a little bit of discussion from our panelists and/or questions from the audience. We'll try to move it along because we want to try and get through a fair amount this morning.

Without further ado, I'm going to start with our first section on commerce, certainly one of the fastest growing areas of the Net study that was released here. A Nielsen study that was commissioned by CommerceNet earlier — was that yesterday? It seems like a long time ago. Anyway, basically what it says is that the Internet users in the U.S. and Canada are wealthier and better-educated than the [inaudible] as a whole and that 13% already use the Internet to purchase products.

So to talk to us a little bit more about this this morning, we have Dr. William Wong, who is currently with Enterprise Integration Technology, which is merging, transforming and going to go with Verifone. He will be Program Manager Rep for on-line payments in that environment. His organization is already a part of AmericanNet and William, if you would like to come up here, I know he's going to assure us that full interactive commerce is just around the corner and that security issues and those key barriers are almost a thing of the past.

William Wong: Good morning. What I'd like to do is, as Jane asked me to, is talk a little bit about security and so what I'd like to do is give you context for my comments today, spend a little time talking a little bit about the requirements of what we term security and then give you maybe one or two case examples of what we've seen already with some commerce state

members who have been looking and evaluating approaches — conducting electronic commerce on the Internet. And then I'll tell you a little bit about some of the challenges that we face.

Most of them are not technological but are more business-process related and infrastructure-related, from legal and governmental restrictions of the infrastructure challenges of going forward.

So, where as a technologist might say security in its variety of forms might be a thing of the past or an issue that already been addressed, I think we have actually a lot of challenges ahead and active deployment and I'd like to open some of those.

So, to begin with, I think the context or context of security actually spans multiple levels. Certainly, everyone a lot of times is fixated over two types. One is message related to the security of passing information across the Internet and ensuring no one else except you and the recipient can view that data. But, as you are aware, there is also network security and a host of security-related issues as well as the message security. All three of those areas need to be looked at carefully when deploying a service or a solution for you and your customers or suppliers that's secure. There's no sense in protecting your credit card over the Net when it lands on your machine and a cracker could come in and examine that particular credit card number on your disk; so fixating over choosing particular message protocol for security is not going to be sufficient.

Now, the specific requirements that we've been looking at for security in general, be it host or network or message recipient, have been the following list — certainly confidentiality is the first requirement that most people think about, making sure that no one else but you and your recipient can view that data. The second very important requirement is authorization, knowing that the message was indeed from the person whom it says it is; you can never tell whether it really came from that person, so today I would advise people who receive e-mail from someone saying please transmit \$50 to me to be suspect of that unless they are verifying.

The third requirement is integrity, knowing that the message was received after it was sent. I think all proxy servers which people are now using for a variety of purposes, including performance optimization, are actually an interesting place for a tax because when people receive a message the first time they get cash on the proxy, then some other person might come in and make a modification to the message and you result get the situation where someone wheels a fake ATM machine into a shopping mall and starts collecting messages. People don't really know. That's a situation where authorization is an issue.

There's also the idea that someone might come in and replace or capture your message and replay them in a slightly different way, and that is an issue of integrity.

And then the last sort of important one is non-repudiation, the ability for you to verify that the recipient did indeed transmit that message and it's authentic. That is the fourth important part of security.

Now, certainly in the first one the confidentiality requirements we talked about — encryption, authentication, or repudiation — we talked a lot about terms like digital signatures. Integrity talks about message, and these are all technological terms for technologists to typically refer to. But I think the important thing to take from those is sort of looking at your architecture of how you deploy your services, either as a virtual mall or as a consumer looking to buy things. The issue here is not significant from point-to-point from your client to your browser to the web server, but as merchants thinking about what happens when the information is accessed at your particular machine. What happens after that [is to figure out] how you control and manage that information, protect that information so that leaks of that information do not constitute a security risk.

Let me sort of give you a couple of examples of what some of the members have been look at and evaluating. There's a very large government agency that a member of CommerceNet has been looking at, hoping to reach out to both corporations and improve their tax business processes, as well as the situations that allow them to be able to retrieve information about their earnings. So, the first issue for the agency was confidentiality, being able to ensure that people who are transmitting their sensitive personal information were able to get that over to that government without anybody else being able to look at it.

But then the next thing was that in certain situations, in certain interactions between the individual and the government agency, they wanted to make sure that the individual was indeed who they said there were, and so the issue of digital signatures became fairly important to them, and who certified those digital signatures became quite important. Without that in place, they weren't going to allow those types of services.

So, looking at specifically the way they implemented things, they looked at secure [HGP] and decided that based on those two protocols — we're talking about the Web in this particular case and how they wanted to interact with individuals — they took a look at those two protocols and decided based on their requirements one of those protocols would be applicable for each particular service. What they end up doing, and they're still in pilot phase, is actually deploying both — looking at whether they needed digital signatures, something that allowed the user to digitally sign a request, and allowing the consumer to be able to verify with the Social Security Administration or the government agency that they would maybe just use a secure [inaudible] and that would be sufficient.

That's an example of trying to separate out, based on their requirements, what technologies we use to deploy for particular services. And it wasn't just one approach; in other words, to secure a tax transfer was just one of them and it wasn't sufficient, or one wasn't the only solution for them.

Another example of a situation in CommerceNet was people looking at supply chain management and having several manufacturers and suppliers using the Internet to share requests for quotation information over the Web. And from that organization that was issuing these request, [there was the matter of] quotations being issued to specific people out there in their supply chain, and being able to authenticate those types of people. And again, showing digital signatures and certification was an important requirement for them, and so they chose one protocol versus the other.

But there are other cases in that situation where all they want to do is just get the people who have the Web browsers to download information securely without — security I mean in terms of confidentiality — without necessarily requiring them to authenticate this with a simple password. And something like Secure Sockets Layer was appropriate for that particular purpose.

I think one thing we have discovered over our pilot projects and our experiences has been this challenge of certification and the issues about technology. People have demonstrated public certification and digital credentials over and over again over the last years.

But the challenge has been in deployment and getting all the software vendors and the hardware vendors to agree on a particular set of approaches, the generating and disseminating and then the merging to certification of your credentials as we move forward.

Let me give you some of the examples of some of challenges. First of all, some people have the idea that there will be only one certificate or credential for you on the Internet. What some of us believe, and certainly I believe, is that won't be the case. Just like you have multiple credentials in your wallets or your purses issued by a variety of organizations for a variety of purposes, we see the same thing happening on the Internet. And if that's the case then the next question would be, what's the equivalent to your wallet or purse in mailing those credentials?

Right now you pull them out of your wallet and hand them to someone, and you get them reissued and you get them in the mail. What happens on the Internet? Do you go to something like a smart card? Does everyone carry a floppy disk around? And what formats do these certificates exist in, and how do you get them? From your post office — and this has been discussed by the USPS — or from your banks?

The worst case scenario that we're facing right now with everyone deploying their own public e-credentials is that we end up with 16 different wallets you'll be carrying, your virtual wallets, if you will. And not only that, but each of those wallets will be for a specific applications, so your Netscape browser will be one wallet, your Spry browser will be another wallet, your Lotus will be another wallet, and pretty soon the consumer will virtually drop their hands off the keyboard and walk away.

So one of the barriers that we are trying to wrestle with at CommerceNet is trying to bring the awareness to the suppliers of software technology, hardware technology and the operators of these credentialing services that while the encryptions have been time-tested, and different implementation of these encryption technologies and digital signature technologies embedded in applications are going to be tested out over the last couple of months, weeks, and years, the challenges for all of the credentials — keys, we like to call them, as in key management, certificate management — is the next sort of challenge for us over the next year.

The other thing that actually is more important, and I think is going to take a little longer time, is going to be the legal status of these key certificates. There's a variety of states who have started legalizing the use of digital credential or the issuance of digital certification; the states of Utah and California have digital signature acts signed by and passed into law.

No one has ever tried these, so no one exactly knows what these credentials, the legal status of these credentials and digital signatures, how they apply, The Internet has no boundaries and knows no boundaries, and so the questions becomes, "if you digitally sign a document and have a public e-certificate issued inside the state of California, does that hold in the state of Utah?" Or worse, does it hold outside the U.S.? So that's what we're facing right now.

So in terms of looking forward, to keep this short talk short, what we see in the future over the next year is certainly more software and hardware solutions coming out. You've seen firewall vendors provide message approaches for their applications, but you haven't really seen any vendors out there doing digital issuance of credentials. I think at the next Internet World you will start seeing some of these folks saying, "So you want a certificate? We can issue one for you to save time."

What we're going to have a challenge with is the key management and certificate management, and the legal questions of the state. When you do electronic commerce, usually legal infrastructure is fairly critical. Actually, when you do commerce in general the legal infrastructure is fairly critical, and probably is the slowest of all to mature; and that's where we see the activity will be in the next couple of years.

With those questions, I'll turn it back over to you.

Jane Dysart: I think we'll move into the banking scenario that we have for you and we'll keep William around to answer some questions after that segment. And now I'd like to invite Jim Phillips to come up here.

He's with Security First Network Bank, and it's interesting to me... I was with the bank for many years, and all of the format has not changed — or the format has changed, but the content has stayed the same. When I was by the booth they were giving away toasters when you open an account. I'll let you talk to Jim.

Eric Hartz: Good morning. Actually, my name is Eric Hartz. Jim is very busy demonstrating our demo so I'm going to give you this talk. I have five minutes I was told [I could] speak, and I'd like to cover five points today about the bank.

Number one, I'll give you a brief history about where we came from and what we are; two, I'll talk about the differences between Internet banking and on-line banking, because there's a lot of confusion I believe among those two; three, I'll talk about security, which is very important and very critical to our success and the success of the Internet overall; four, I'd like to talk about where we think nets are headed in banking rather than just what we're doing today; and five and finally, if you're interested in signing up for an account, I would go ahead and do that. These are pretty much the order of the questions we've been getting the last couple of days.

The brief history... You know, a date has to make history, and October 18th of this year we became the first bank on the Internet. We are a supervision-approved, regulated, bank — insured, the whole works — and on October 18 we had our first transaction. We made a donation to the American Red Cross over the Internet, and so of us that was pretty much history making.

A little more history is that our true founders are two different individuals. One is a CEO by the name of [Chip Mayham] of a company called Cardinal Bank, which is a publicly-traded bank. The other, his brother-in-law, is the CEO of SecureWare, which is a security software company that has been working with the U.S. government for the last 10 years. They've pretty much been reworking unichex systems, removing root privileges on unichex systems so that there is no access, and so what they've done is handle B-1 and B-2 Stealth bomber flight plans and things of that sort for the last 10 years with the government.

These two were talking for a quite a while, and one said "Gosh, Internet is very hot, commerce is very hot, we have both the backgrounds to bring banking to the Internet with the banking and security experience." So that gives you a background about why we came to be and where we want to go.

The difference between on-line banking and Internet banking is the following: a lot of on-line banking services require some type of purchase of software that you have on your computer at home. You buy the software, you load it onto your computer and then you can access a bank account, or a variety of bank accounts if they're partnered with that software company.

With the Internet each one is completely fluid. All you need is a Netscape browser and Internet access, and you get our server and you do all your banking right there. We have the interface for paying bills, we have the interface necessary for moving your money around. When we want to do a software update, you get it the next day. There's no new versions that are coming out over 6 months or so, so you're literally on-line.

Second, with the Internet, it's obviously the reach. If you're traveling a lot and you're all over the place, if you can access the Internet you can do your banking. A very good example or indicator of this is what people in the military have pointed out to us. [They say], "If I get stationed abroad, let's say in Italy for six months, that means I've got to prepay all my bills, I have to give power of attorney to somebody else and then I come back and often that power of attorney has been exercised against my will and my bank account is empty." They now can go to Italy and do all their banking as if they were present in the U.S. because they're accessing their bank in real-time over the Internet, so it's a very powerful tool.

The third thing is security, and that's obviously the most important. We have tried to explain this a dozen different ways — and I realize there's all kinds of experience levels in this room, so I apologize if it's too confusing for some and too simple for others — but we have three levels of security or three layers of security. Between your computer and our firewall, we

like to use the analogy that that's the armored car. You give your money to an armored car, they lock it in, they travel over the Internet to the firewall. The equivalent technologically is Secure Socket Layer on the Netscape browser.

Right now we're going to the 128-bit key version that we would be sending out, and we use the RSA-licensed public/private key encryption approach for that. I'll talk about the break [in that encryption key] in a moment and how, frankly, that would not have impacted our bank in any way.

So once you get the armored car to the bank you need security between the vault and the truck, and that's the firewall. We have a technological firewall system, and I won't dive into all the details, but again SecureWare, our sister company, has been working with technology for a long time. And because SecureWare is also our founder, we have exclusive license to both SecureWare technology and what they've been working with. So that is our security guard at the bank — they guard your money, they're armed protection and they get it to the vault.

Finally, and most importantly, is the vault itself, and that is our bank server. It is a base system that SecureWare developed; we took the exact government technology — it's called a "Secure Web Platform" — that has in essence replaced all of the root privilege approaches that the current systems have in place. We have eliminated root privilege and replaced it with 52 bracketed privileges.

Let me just talk about that very briefly. If you want to go into a system, if you find a way... Let's say we've eliminated all of the Netscape [security] and firewalls and you got directly on to the server. Since there's no way to access any root privilege, there's no way to access any within the server; a whole different set of codes and different set of approaches to do it. If you're clever and say, "Gosh, maybe I'll just try to change the time and date, they probably aren't protecting that very much, and if I get in there I'll find a way to get privilege and do other things..." But it's 50 layers of security that we've put in place, and as you get security for each — excuse me, privilege for each — each operation that you do, say if you come in to change the date and time, you'll get privilege 49 out of 50, and it doesn't allow you to do anything else, it's only for that single operation. In order to do a definite operation, for instance a bank transaction, you would need privilege number four, for instance, to get that high in the system.

The other thing as far as weaknesses go — because any system has a weak link, and we have to make sure we've covered them. We don't believe that technology is a weak link from what I understand. We believe a weak link is a diligence on the consumer side. A lot of people put their four-digit PIN code on the back of their ATM cards. A lot of people stick passwords on a computer because they don't always remember them. We've done two things on that front.

One, we don't have a name and a password log. We use your social security number and then a password on top of that. Friends or even colleagues around you don't know that social security number, so at least they can't immediately get your password and get access. Obviously if they get both they can become you. If they're sitting at your machine, they know your social number and they know your password, they, in essence, are you now. That's where the second level comes in on the server side. We use similar approaches that ATMs use that would cap movements in your account, and we also check spending activities since we have e-mail and voice connections. If we see suddenly that there's a five thousand dollar movement of money and you've been spending 100 dollars a pop on different bills, that's going to raise a red flag for us and we're going to contact you directly before we make that transaction.

The other obvious weak point is on the administration side. Someone's gotta know you to use the privilege system we developed. We are working on or already have in place [a system] where you don't have a single individual responsible, so that way there has to be whole kind of collusion in place, if you will, for that to occur.

Now, when you compare this system to the current banking system, which is the real story we're trying to get out, this is very much safer. We've seen examples with a bank with a billion dollars worth of assets having \$20-40,000 a day in losses. Now we, like a regulated bank, have a hand on our banks, so we're insured from that point of view. We also have to have C insurance, although we had zero impact at all, not 20-40 dollars a day — not even zero — so we're pretty certain about the security so far.

The fourth thing I want to talk about is where are we going with this. What does it mean in banking and commerce? We think banking is just the first step. This is, frankly, our baby steps to get started with commerce. Our vision of the future is to bring your net worth solution to the screen. I would really appreciate if I could bring a screen up and say "here's your bank account information, here's your brokerage portfolio information, here's your insurance information, here's your loan information," and have it all on one screen together. You can do transactions among the different functions. You can buy insurance on the Internet, you can do brokerage and interest, you can get information about your portfolio all in one place. We think that's very powerful.

Also, as we see bandwidth expanding we currently have customer service reps 24 hours a day, 7 days a week, 365 days a year. If you want to do your banking on Christmas day at 2 AM in the morning you can call somebody or you can e-mail somebody. When video capabilities come down the road, we would love [to use them] and we would be in place to place a little box in your upper corner of your computer that says "Hello Mr. & Mrs. so-and-so, how can I help you today?" You have an image of a person and that should bring some relationship and interaction with humans back into banking. We think there's a way to do that.

There's also a way... There's a lot of activity with ATM machines and kiosks with this software, and they're effective. However, selfishly, we're not trying to just be a bank, we're also going to be a whole other business, and for that we have regulatory approval. We have a wholly-owned software company called Five Paces Software, and we're selling and licensing this software to other banks that want to be on the Internet. So what's happening is that if someone says "Hey, I want to be on the Internet," and they would rather not partner with someone like Quicken, where their brand is always on the screen, we're taking a very open model and saying "Great, if you want to be on the Internet, we'll redo the whole Home Page for you, your brand name appears, you own the customer and if you'd like you can use our partnerships or brokerage in insurance." But if you have your own partnerships right now, let's say in insurance, and you only want our brokerage that's fine as well, and we'll integrate what you need to put in place.

So we're going to also try to accelerate the trend not just by being the first bank on the Internet in keeping our own name, but helping others get on the Internet as well. The other thing that we would like to do going forward is with e-cash and digicash, and that's creating kind of "debited" cash for you to spend on the Internet. We think it would very powerful if you have your bank on the Internet, and you're shopping at the market and today, rather than write a paper check for someone and hand it to them in the store, you can write an electronic check sitting in the store with them.

A lot of the companies out there... For example, I was talking to Open Market, and they have a lot of relationships with different merchants. We can set up a verification system with our bank just as you would with a credit card company, and they could contact it and see if you are the right person and say, "Yes, you have a balance to write this check and therefore we accept it." So you've in essence created electronic cash in that way without having to create a special system for doing debited digicash and e-cash. So that's a vision were we see things heading.

We've also tried to make it — this is my fifth point — easy to get an account. We just need to go to the obvious. You can go to the obvious; and just to show you a little bit of the flexibility, we've added for the 18th, for our grand opening, what we call "terminators," — balloons, laser words, etc. They weren't that way before. You go there and you can demo the account and how it works and then literally go and open your account.

When you click on Open Your Account, you go into secure connection and then literally just fill out a form. If you went into a bricks-and-mortar bank tomorrow and said you had to fill out an account, you would do the paperwork and that would be fine and then you'd hand it in. Here you do it securely, though for regulatory reasons you need to print it out at your home because you need a signature on file. You have all seven PIN codes here, you have all the other private information, you put a check in an envelope and your off.

We've set up a fee situation to help people get on the Internet, though some people are going to think security is [inaudible], or they're not sure about commerce, so they don't want to be party to what is valuable today.

We are actually offering no-fee checking, no minimum balance, no fees on your ATMs and 20 free electronic payments per month as well. Other services charge \$10.95 per month for that. We say up to 20.

Most people in pay eight to twelve bills a month, so that's fine. Also we send you a bunch of envelopes for your deposits, and they are already stamped. We want to make this as easy as possible because we believe when people start using this and getting the first [inaudible] of the bank that they will see how powerful the Internet is, and a lot of the other exhibitors that we see out here today will help this kind of commerce and global village really occur. That's our goal, and what we're trying to do.

Jane Dysart: I think to keep this moving along, what I'm going to do is say if you have any questions for William, you can find him at the CommerceNet booth, and if you have questions for Eric, you can see him at the Security First Network Bank booth, or just take out that map that we put in your program and go directly to those booths to find or to ask further questions or see more about these particular products and services.

We're going to move on into a section on tracking. So, in order for the content on the Internet to grow and to merge, and to attract new customers to be really appropriate to all our needs, it's really important to know who's looking at what, to take the pulse of various Web sites and to measure what's happening; so our next speaker that I'm going to invite up is Paul Grand, who is Chairman of the Board of NETCOUNT. He is very interesting, he looks pretty young, and he looks pretty scary to me, but in his bio [he says that] when he was 13 years old he helped start an educational software company, so there you go. He has also been involved in a number of projects in the film and TV industry, but what we want to hear about today is the Web site tracking services that he's involved in called NETCOUNT.

Paul Grand: Good morning. We're actually at a very interesting time right now because this is our actual first week of selling our product since we developed it about 8 months ago. We spent a great deal of time analyzing the needs of both the Web site environment as well as the advertising environment that wanted to place advertising on the Internet.

We ourselves came from a background of Web site development. We started a company last year called Digital Planet which is one of the largest providers of entertainment content on the Internet. Some of our original clients were people like MCA and MGM, and we were developing sites for them and they would say things to us like "how many people are coming to our site? We want to see if as many people are coming to our site as going to our

movies, see how it affects ticket sales.” So we started writing some basic tracking software for them.

Then a little later they started getting phone calls from people saying “We’d love to place an advertisement for you on our Web site that would also generate traffic to your Web site.” And our clients would call us and say “hey, it’s worth it.” And we’d say “What kind of traffic are the sites getting?” They would make phone calls and people who would answer would say things like “We get a million hits a week,” and of course, we all sat around and say, “Well, hits don’t mean very much.”

We are now using things like spacers that are invisible, and when hits become huge we’d look and weigh all results measuring the amount of traffic coming from your Web site to our client site and they said, “Well, we really don’t have any kind of solution for that.” You can create a special page on your Web server that will link from our server, and that way you can measure the traffic to our page.

We said “What if people start bookmarking that page with a pass, and what if that page gets listed on a ‘What’s Coolest’ somewhere? Suddenly it’s going to look like tons traffic coming from a banner that’s not generalizing it.” They said “I’m sorry, we have no other solutions.” We said, “That’s really not an acceptable answer.” We felt that for our clients we would write software that would let them monitor the performance from the billboard to your Web site and just charge back that traffic.

We started developing the software and we offered it to our original clients, who were pretty happy with it. And after a little period of time, I woke up one early morning when I couldn’t sleep and I said “If we could pass this out all over the Web we could track the Web,” and that’s exactly what we’ve set out to do. We spun off a company several months ago and became a separate corporation called NETCOUNT. Now I’m Chairman of the Board of that company, and I lead the company in terms of strategy and direction.

What we’ve done is assembled a pretty amazing team who have developed software that would allow us to do something that no one else would do right now, and that’s actually track Net users. I’ll give you a little overview of our services. One of the first things we realized was that there are lots of sites out there who have tons of traffic, like a company like Yahoo who was originally run by some Stanford students who don’t have millions to go out and spend. Well, they do now but they originally didn’t have millions to go out and solicit people to place advertisements on their sites, so they couldn’t go out and place advertisements — and I’m talking about an IP address now, about individual people who are coming back to a site.

Our software allows us to watch and see who’s coming to a site and going back over and over again. It also allows us to watch somebody going from one site to the next which allows us to really truly monitor the performance of a billboard.

Right now if you are paying for a billboard on any Web site, you might pay some 30 dollars to have an advertisement. The question is, is that advertising performing? Someone could, if they wanted to, give you numbers; they could sit there and see how many times somebody clicked on that advertisement, but the question is that one person clicking on it or was that 10,000 people clicking over and over again. It could be a program that someone wrote to click on it over and over again.

What we do is we have a service for someone who has advertising on the site, we give them a list of the actual number of times an advertisement was deployed, how many people saw that ad, how many people clicked on the ad, how many people actually made it from the ad to the site because for an advertiser who is trying to drive traffic to their site, they need to know how many times someone actually gets to their Web site, not just clicks on a banner somewhere else.

We've even seen cases where there's been blockage roads, the time when you can't get from the advertisement to the Web site, as high as 25%. That's a pretty high number. You really want to know how many people are making it to your Web site. Our software lets you do that. Then we thought it's really not enough even to [inaudible] users, which is a wonderful thing because no one has done that before. There's one elusive thing that people have been waiting for and asking about but have been unable to receive...

[Tape change]

Paul Grand: ...and that's demographics. Authentication and giving out digital IDs is where someone has a record of what you're doing, and that's something that's very scary to the Internet audience.

Right now people are all worried about someone going in and getting a subpoena for their records from video stores to see what videotapes they rented. On the Internet, it could be a lot scarier. Someone is really able to record what that you do over a period of time and, trust me, people will ask for that information if it is available. The system we designed, which is part of NETCOUNT's *Head Count*, allows users to remain completely anonymous.

The idea is that instead of going to someone who issues a digital ID who keeps databases and saying "Okay, these are the names of the people, here's their..." you can just provide your ID at the time when you come to a site. We design a system where no one will ever have to present an ID. It's done completely automatically by them by their browser.

The idea is the very first time a person is seen by us at any of the sites that are learning our NETCOUNT software, any of these sites, that person is asked the very first time by that site to fill out a form. This form is not like some of those forms you may have seen already that ask you everything from your income to your age to your occupation to the company you work for, your mother's maiden name — we don't do that because we consider that to be truly a privacy issue. That would mean we'd have to get that database information, and we feel that wouldn't be a really good thing today.

So instead what we did is asked people to provide us with basic information like the street address and their zip code. All we do is we match up the street address and the zip code for the household demographic, the information and the street address and all we're left with is a demographic and an ID. That's it, we don't get anything else in our databases so we can never actually say this is the user is who is coming on your site. Once a person has done this they are never asked to fill that form out ever again, anywhere else. They're never asked to fill in an ID code to go from site to site, there's no password box. They can be completely transparently tracked by us and we can report demographics.

So what our system actually gives you is a report on your Web site, which is very detailed, which like I said measures page transfers, even on an hourly basis, so you can see what pages is on your site are the most trafficked pages, what time they were transferred and how many people saw them and even the demographics of the people who are looking at it. And that's something that's never been available up until now. The idea is that we want to get a complete and total mass of traffic coming through our machines. We want to know what's happening on all the sites on the Web.

Once we've gotten all this information, we have a service called the NETCOUNT Rate-and-Rack Intelligence section. What the rate-and-rack intelligence does is it lists the sites that we are tracking by industry category and it actually breaks down the volume of traffic that's being reported by those sites. It's very comparable to something you'd look at in a magazine and see how different TV shows did last week, or how the different movies did in a box office.

What we do is we list just the volume information; no detail, no information about the number of users, we don't actually tell you the demographics of the users. We just give volume statistics, so you can compare all the sites. The idea is that when you're a person who's in the media research industry or a person who's trying to place an advertisement on the site, or you as a Web site are looking for somewhere to place advertisement, you don't want to have to call up ten thousand Web sites and say "what's your traffic?" You can come to one simple place on our site, they type in the search parameters they're looking for and they're able to receive the site that matches their category.

Once they've got that handful of sites, they click one more time and they can get a rate card for each of those sites. That rate card listing and that volume information is provided by us for free to those sites. So conceivably, a site can come into us and say "Hi, we're so and so and here's our URL," and we give them the software they need, they get the information transferred to us, we process it, we list them in that rate-and-racking intelligence section with their rate card and they haven't paid us a penny, yet that site is now ready for advertising like any other Web site.

It also enables you to compare how your sites are doing to competitors, which is something that a lot of people have been waiting to do. You're able to look and see how is my Web site affected by what my competition is doing. Someone comes out with a site that's generating tons of traffic, and it's really exciting — they got a brand new promotion, traffic on your site is probably going to drop, and you want to see that comparison. We can actually provide that now. The way the service works for us on a subscription basis is the people that want to get into the rate-and-rack intelligence section pay us a monthly subscription rate for a certain volume of reports. They come in, they can run standard reports which list just by industry category, or they can select custom reports which costs more in terms of record units, but provide searches across all categories, across demographics, and even across user groups.

So we're able to actually provide for the first time a service where somebody can say "How is my site doing and how does that compare to other Web sites?" What this is enabling now is several different things. Besides just measurement of your own site, people are able to do things like now just actually compare how advertisements are doing so if people place 5 different advertisements on the Web, you can see if this one is working vs. these other four, so maybe I should stop using this Web site and use another one. It also changes the way advertisements can happen on the Web.

Right now the current model is that you see people paying \$30,000 for a billboard on another Web site. The problem is that if you have a limited budget then that means you can only place a couple of ads. We designed a system where it actually authenticates the people who are being handed off from the advertisement to the Web site, and we make sure it's not the same person over and over again. The idea of this is that people can actually now start billing on a per inquiry basis, so instead of saying I'm going to give you \$10,000 or \$30,000 for an advertisement, they can say I'll pay you a couple of pennies per click, or actually per user that's coming across. And that's authenticated clicks, they're not just one person clicking over and over again.

Taking it even a step further, someone who is actually selling product on the Web site can offer a commission to a person for placing a billboard. So conceivably a person can place a hundred billboards on the Internet and they can pay all those people commission on the sales on their Web site, and not lose anything. They're actually gaining, they don't have to worry about throwing money out the window, which is basically they could be doing right now.

So it's a system that's available. You can come down to our booth and take a look. As I said, it's available for free as well, so anyone can get started and whenever you're ready just drop up to paid service. Thank you very much.

Jane Dysart: Thanks a lot. This is a real challenge for everyone; on the one hand we want to be able to get you a lot of information and whet your appetite for some more, but on the other hand we want to move through a number of sessions, so it's quite a challenge.

We are a tad behind, and we're going to move on to look at filtering that's so necessary in today's highly electronic and information age. With an estimated over 40,000 Web sites, it's really often very difficult to deal with the volume. I'm going to actually rearrange these just to make Hope's life a little difficult because one of our speakers has a plane to catch shortly, so we're going to actually start the filtering section with Rob Glaser, who is progressive and CEO of Progressive Networks, and he's going to represent PICS consortium, which is the Platform For Internet Content Selection.

Rob, if you'd like to come up here we'd like to hear how you're going to revolutionize the filtering content for child protection.

Rob Glaser: Thank you very much. I appreciate the invitation. What I'm going to do today is recapitulate in rapid speed, although I probably won't talk quite as fast as the preceding speaker, but I may come close.

An announcement that we made on Monday here will sort of give you a little context about what the announcement is all about and where its going.

What PICS stands for is the Platform for Internet Content Selection, and it is a vendor-neutral, platform-neutral, content-neutral framework for describing and characterizing for the Internet. The genesis of it was actually that several of us realized that the Internet was becoming a mass media.

My company creates software that makes audio and multimedia practical over the Internet, so we sort of saw the issue square-on and we got companies like Netscape and Microsoft — who obviously have very significant positions in Web browsing and access operating — to just say that, in the context of things that are going on in Washington D.C., the government was saying "Well, gosh the Internet is becoming a mass medium, kids have access to it, kids know more about it than their parents therefore we gotta censor it," and we thought that there was a different way.

We thought that there was a way to preserve the diversity, creativity, vibrancy and energy of the Internet, while at the same time creating technology that enabled the legitimate interest of parents and educators to frame the media environment, if you will, that their kids saw. And this was really one of these cases where you could really have the best of both worlds, but we needed to act fairly quickly because the government was marching. And also we needed to act in a industry-wide way.

So we pulled together a project that we originally called "The Information Highway [inaudible]" and with the Paramount Group announced an intent of the three companies to create a standard of specification; and a couple of months after that we pulled in about 25 companies that were working very closely with the WorldWide Web consortium out of MIT to create an industry-wide group.

We now have about 25 members that are creating technical specifications for how content filtering will work with Web browsers, newsgroups — it's a generally wide framework for getting content into your PC. What we announced Monday was the initial publication of technical specifications, and if anybody wants information on those specifications, go to the

Web site that was on the page previously. It WWW.W/ORG/PICS, all capitals. I think we're on the top-level page there.

And that is the place on the Net for you to get more technical information. What I'll describe now is basically sort of the essence of what we're doing, what the road map is for the next steps. What we've published is a way for any third party to produce what's called a "rating system" or a rating service based on one or more rating systems. The content of a rating system we'll all familiar with; you know, we're familiar with what you could think of as an extreme rating systems like the way the Motion Picture Association of America characterizes its content in a very monolithic way. The whole movie is either G, PG, PG-13, R, NC-17, etc.

So you have the concept in that case where there is one category, if you will, an overall rating and then there will be four or five descriptions within that category. But given that computers are very good at filtering in all kinds of different ways, it seems to us we wanted to have a more generalized framework. Instead of it being one category we wanted it to be three categories, 30 categories, ten categories, whatever the person characterizing the content feels is an appropriately way to characterize information.

So, for instance, to describe another rating system that is supporting PICS, the Recreational Software Advisory Council has a system that they use for video games describing content based on three criteria: based on sexual explicitness, based on violence and based on language. And for each of those categories there's a rating scale, sort of akin to G to NC-17, ranging from tame to strong or explicit and in that case it lets the parent or the educator characterize the content they want the kids under their supervision to have access to.

So that kind of approach, a generalized framework is really what's behind PICS, and the announcements of the specifications describe the framework, really a technical specification for how anybody could put together a rating service. In fact, the day after we announced on Monday the first of what we hope will be a number of third parties — there are some third parties that are in the PICS consortium but even a new one that we hadn't even known before hand had announced — a company called Internet Filtering Systems announced a scheme that goes even further and allows people on the Web themselves to vote for rating systems.

So that's exactly the kind of spirit that we're trying to get, the notion that the Net will move to a model where there are multiple rating services, where *Parenting Magazine* might have one, *Good Housekeeping Magazine* might have one, your local PTA might have one, the Christian Coalition might have one and then parents and educators would pick one that most closely is tied into their values and their sense of what was important.

People ask us how the economics for this will work, and our answer is [that it will work] the same way it does on the Net. There will be some people that do this on a voluntary basis, both providing the systems and the services that hook your computer into them, or other people will be doing it on a fee basis.

A number of the companies that are involved in PICS are companies like SurfWatch and NetNanny that are already delivering products, like PICS, that deliver their own systems for their own services for doing rating and tying in your [inaudible] browser or your access software into these rating services. All those companies — in fact all the ones that we know of — have announced that their planning to support PICS either by running their own rating services or by selling the systems to consumers and parents and teachers and the general public.

Well, just to kind of lay out the timetable from here, we announced that we have about 25 members in PICS, and our most recent additions are Digital Equipment Corporation and New View, and you get the full list of members on the site. We announced about 15 additional companies that announced themselves as supporters, and one of the things that is really exciting

about that is that they are companies like NEC and France Telecom — which has clearly given the global nature of the Internet.

For something like to take root it has to be a global system. That's one of the problems, frankly, with these domestic legislative solutions; they try to ban and censor stuff on the Net, and it won't work because you'll have all these services out in Belize and other places. So clearly, for something like this to work there needs to be global cooperation, and I think we made good strides towards that end.

The next upcoming timetable for what we're doing is to release the draft for the initial technical specifications for how you characterize a rating system. That's already up, and you can pull that off the site. We will be, by the end of the year, putting out the draft specifications for how you transmit those rating systems, and there's a whole set of approaches there. The rating system can actually be with the content, so in other words you the content provider characterize your content yourself; or it can be a third-party rating system that's delivered on the Internet, or a third-party rating system that's delivered off-line, say on a CD-ROM or in some other methodology where it's published on a regular basis, and that specification is to come.

By January we'll have the final specifications and also a sample reference code that PICS and will release in a totally unencumbered way to the industry. The next step after that is up to the industry, to have the leading software companies build this capability into Web browsers and Net access products, to have the third-party services and the third-party rating systems actually embrace and support the system. We'll be doing a lot of work in the days and weeks ahead, and we're very interested in your help and your support, and the industry's help and support, to turn this framework which is off to a very promising start into an actual end solution.

The whole legislative environment — speaking very candidly — in Washington D.C. has not gone away, and our announcements have had a very positive impact on the efforts of the folks who don't want to see a government censorship approach. But the government censorship approach in the form of the Communications Decency Act was actually passed by one of the two Houses of Congress, by the Senate, and it is still pending as a possible solution if we as an industry don't move forward aggressively and energetically; so please encourage anybody who is not currently a supporter of PICS to get information and sign-up. We have, if anybody is interested in getting access to technical information, information on the site on how to get access to technical information and to contact the technical committee.

I personally chair the committee and would be happy to share any information I can. My e-mail address is robg@prognnet.com and we have some PICS information at our booth, so if anybody is interested in this information leave your card and we'll send you on information.

Again, we want to thank the conference for giving us a chance to update you on what we're doing. We really strongly seek your support, because I think that together we can maintain the openness, diversity and creativity on the Net and do it in a way that makes it a safe and appropriate for parents and educators, and honestly not have the government get involved in a way that would be really deeply counterproductive. Thank you.

Okay, we're going to continue with filtering and bring Roy Ang from Qualcomm up to talk about filtering our e-mail, [which is] certainly one of the most popular activities on the Net and something that I think we all need to help in doing. This product that Roy is going to talk about comes from *Eudora*. Can you reach the microphone?

Roy Ang: Good morning. I'm from a company called Qualcomm. I'm hiding, so you can't see me. We specialize in a number of products, including digital cellular as well as GPS and satellite work, but the product I'm going to show you today is called *Eudora*.

What I'm going to show you is the filtering capability of *Eudora*. As of the latest figures that we got just before the show, there are some 11 million users *Eudora* now. I don't know what your days are like, but I can walk in on my job and have between 250-300 messages a day, which is pretty horrendous.

So what I've done is I've brought in an example mailbox. This mailbox has mail from all different groups, and what I've done is labeled them so I can tell which groups the mail came from, which ones have attachments, which ones were rated as high-priority by the sender, which ones are read and which ones are unread. Because I end up with so much mail it's almost impossible, if I came into an in-mailbox like this, to know what is important and what isn't; so what we offer is some pretty industrial-strength filtering, and if you come down to filters here, what I've done is I've set up a filter. I haven't searched for any incoming mail, so it will, automatically on the fly, as it hits the in-mail box.

I have it set so that subsequently I can go back and check any mail, any mailbox at any time and apply these filters as well. This pretty simple filter just searches the "to" line, but you have a choice; you can search the to/from subject, carbon copy/reply to or any heading, applying the esoteric headers for folks who don't pay attention to them anywhere in the body of the message.

I have it search for a particular string — in this case it's Jackie, but you can put other rules to it — with [a string of] contains/doesn't contain, /starts with/ends with and on and on. I can then apply a second rule here if I wish, but in that particular case all I want to do is just label. I've decided to label it "Personal," and then I have it automatically transfer into another mailbox. In this particular header I've made it a little more complicated — actually, no I haven't, let me turn this on... This one, again, automatically sorts any of my mail as it hits the in-box, and I can go back and search any other mailboxes. This one is searching in the header. Again, it's looking for Jackie, unless — and you can ignore and or unless — unless there's also an attachment enclosed, and if that's the case I'll send it straight to my marketing mailbox, automatically on the fly, without my doing anything. And [it will] also color it.

Now, if I want to apply the filter as soon as your mail hits the in-box you don't have to do anything; however, we'll take the case where I didn't apply the filters, I just created them. This in-box looks pretty scary. What I decided to do is select them all, and then, if the mailboxes have unread mail in them, what I've done is create a hierarchical structure here. I've worked [inaudible] and then I split it up into Engineer Work and Marketing, and apparently I have some messages.

If I take a look at any of these messages you'll see that they meet the criteria here. So this is an example of what I can do.

In addition, what I could do if I wanted to is add some other features to the product, where you can select a bunch of messages and change at any time the status of those messages, what you think you should apply to it after you've read the message. Right now what I'm showing you is version 2.2 for Windows. Our 32-bit version should be finished in November, and we anticipate that this should be up by the end of the year. The filtering capability in a ruling is quite more extensive. For those of us who don't have very much time, this will save your life.

If somebody comes up to you and says quickly, "We have a meeting, we need to go over all the things that we discussed in marketing last week," if you're looking at 300 messages, what are you going to do? Chances are that you probably can't hit them very quickly and you can't print them out very quickly; by being able to segregate them this way and organize it, it helps a lot.

I invite you to come by booth if you have any other questions. This will function under Macintosh or any version of Windows, and we also supply the server side of this. This is a POP 3 client. Thank you.

Jane Dysart: Thank you, Roy. Definitely stop by to see and hear more about filtering, and about your e-mail and managing it. Our last speaker on filtering is Rusty Williams, who is vice president of New Internet Ventures with Individual Inc. He's going to talk to us a little bit about filtering resources, all of those resources that are available out there on the Net and focus on content, which is particularly relevant and important to us.

Russell Williams: Hope can be a good enough wheelperson; I'll speak from the podium. I'll quickly give you an overview of Individual Incorporated.

Individual Inc. is a leading provider of news services to businesses and individuals worldwide. We focus on the business-to-business market, taking over 650 information sources — including newswires such as Reuters, AP, Kyoto, Phillips newsletters, EMP magazines — it's a long, long list of information that we take and we filter, using technology that we licensed from Cornell back in 1989, called Smart Technology.

It takes all this information on a daily basis, sifts through it and finds information that's relevant to specific subjects, to specific industries and specific topics that you could use on an individual basis to track on a daily basis so that you have only the information that you find relevant to your interests; so this is sort of a big step forward in the effort to help you with information overload in a sense that there's so much happening in this industry, and we are making it our goal to make information more personalized to your needs.

We have several products. What we'll be demonstrating today is a product called *Newspaper*, but actually our flagship product is called *First*, which we will sell to large corporations where they have needs to track competitors, to track industry trends and other information. We will go into an AT&T or an IBM or other large corporations, and we'll sit down with them and say, "What are your information needs?" And we design a customized solution for them that appears on their LAN, either by Lotus Notes or by Collabra or by Web Platform. That's actually still our flagship product in helping the business market satisfy or solve this information overload problem.

The second product we've developed is called *Heads Up*, where on an individual basis you can get by fax or e-mail the same information delivered to you on an individual basis, where you pick again from these topics that are pre-filtered and sent to your mailbox every morning.

And finally *Newspage*, which is what we're demonstrating at our booth, and what is certainly most pertinent to the topic here at Internet World. It is our WorldWide Web site that we developed about six months ago. It's a fairly new entry, using the same technology, using the same information sources and making it available on the Internet; so, there's *Newspage*.

As an example — are we up at the search screen? Let's type in "Internet World" as an option to see what types of information and what new issues have come out about Internet World over the past day. Did that work? And after we do this, we return to the main menu; you see the main menu is categorized by industry... we have Automotive, we have Banking And Finance, we have a long list of industry characterizations that we've built up information sources for to help people in those areas.

So when we return after this brief demonstration, we'll see that again we've tried to categorize by vertical market, and again we have sales teams that will go out to companies in those industries; but also this information is available to anybody on the Internet in this way, so — I can't read this very well — but there are several stories that have come out from different information sources. You can see one from *Information Week*, the next one is from Knight-Ridder Information Services, and *Communications Week*.

Again, these are all pre-filtered by this technology and an editorial review board as highest-relevance, given the highest ranking related to this topic that we've typed in. You can click on this and you're seeing a summary of the news story, which is primarily the first two paragraphs of the story itself so you get an essence of what the story is about; then if you click on the underlying hyperlinked title you will get the full story itself.

This is where... well, we've actually typed in our user name, but you need to register for this site, but in this case we've gotten the full text of what is the article; so if you're following the Internet World and you want to find out about what's been published about it, here's a very quick and easy way to do it.

Again, I apologize for moving at a rapid pace, but I know we're behind in time. Why don't we return if we can to the main menu, and I'll show you the normal way you would navigate through this and you can see the industry categorizations? That probably is the best place to start there. Scroll down to where we can see the industry options.

One thing is most relevant here — I'm reading a little bit at an angle here — but you can Consumer Electronics, Insurance, Automotive, Energy, Semiconductors; most of this is slanted toward the technology and finance, industries that are rapidly changing and have very strong "need to know" on a current basis. So that's where we built our franchise, and we're building out from that.

Let's look at interactive Media and Multimedia, which is the third button down the left. You can see that through there are several subcategorizations that will allow you to pick more specific areas and will allow you to pick on a personal basis — and Hope, you can pick whatever one you want. You'll see there's several stories, and what you can do is just bookmark these stories on your own depending on what your tastes and preferences are so that every morning you can log in, find information that's relevant to your interests, and again see the summary and quickly get that tidbit if that's all you really need, or get the full story if you want.

I would imagine people would be asking about the pricing for this. There is actually a free level and there is a \$395 level, and there is also — what you need to know is that there is also different levels of sources that we have. Obviously Phillips Petroleum, or *Phillips Newsletter* has a much higher-level source than *PR Newswire*, so we have... in some cases there are stories you have to pay for in order to get them, but the vast majority, if you're at the \$395 level, I'd say about two thirds are available at that fee.

So it's a very low-cost service, and in that case the way we've done that is that we've started to integrate advertising, so that people such as 3Com or Silicon Graphics or other companies that have a very strong interest in reaching this market or reaching these people that are actually reading about this, that are starting banners, we're supplementing our revenues with advertising and sort of driving down the subscription costs, so we're moving into a whole new model with this service.

I think that's a very rapid demonstration, but I appreciate the time and the opportunity to speak with you.

Jane Dysart: Okay, now we're going to move into generation tools and we're going to start with Microsoft. While Steven is getting organized, I'm going to let Hope set it up.

Hope Tillman: While we're setting up, let me talk about generation tools. Actually, in some cases we wanted to have representatives from several products that were not able to send reps to you, so you're going to have to go back down to the booth. For instance, some of the hot products that we saw on the exhibit were *Netscape*, and I'm assuming most of you who have sat in on one of their sessions probably would want to do so with the *Navigator 2.0*, which also has the hot job of being the very hot booth. For some Microsoft Systems is another one.

Microsoft was very kind to send someone and we really appreciate that, because we know how hot the floor is; so many people are on the exhibit floor that we really appreciate those vendors who have taken the time to come up here to speak.

Steve Linowes: I'm Product Manager with the Windows 95 group. What I want to do today is first thank you for coming, but also to let you know about all the Microsoft products that we have. We'll be specifically focusing on something called the *Internet Explorer Version 2.0*.

First of all, people who have come to this show probably have noticed a big change in Microsoft. If you were here last year you'll notice our booth probably went from about 3 or 4 stations to about 20 or 30 stations, and that's just an example of Microsoft's commitment to the Internet community. We're really embracing the Internet, making it very easy for people to deliver content and also view and offer that content out on the Internet. So that's really a high-level overview of where we're headed.

Some of the products that we're displaying in our booth right now are... one product is code named *Gibraltar*, which is an NT server-based Web product. As a matter of fact, the Microsoft-based Web page today is being delivered on that particular server, so it's in data right now.

We also have a couple of great authoring tools. One is *Word Internet Assistant*, which is an add-on for the *Word* product. After all, most of the tools that you see on the floor require assume that you don't already have the content. With *Word Internet Assistant*, in order to create a Web page all you have to do is do a file save on your regular word document and it automatically becomes a HTML document.

We have a product that's called, *BlackBird*, which allows you to do real-time authoring of information, dynamic information, and I encourage you to go take a look at that. That happens to be one of the most trafficked sites in our booth, people are very interested in that.

We also have a couple of other things. One is the Microsoft Network, and the Microsoft Network actually has full Internet access and will be an environment where you'll be able to see great content from the Internet. We also have a technology that allows you to do secure transactions out on the Internet. It's called Secure Transaction Technology, and that can be viewed in our booth.

That's kind of an overview of the products. I'm obviously not going to have time to show all of them, just one of them, which is the *Internet Explorer*.

Now, the *Internet Explorer*, when we were designing it, we really wanted to make sure that it was easy to set up. That was one thing that people were telling us was the really difficult thing to do. How many people have had problems setting up, getting access to the Internet? Not that many people. Okay.

Well, it's a really easy thing to get access to the Internet. I'm not going to show you that. We also wanted to make sure that it was easy to use and easy to learn. We also wanted support for all of the industry standard at the Internet conventions that you have, like for instance, "Tables" is the factor standard. At the same time, we also wanted to make sure that we were delivering performance and innovation, and we're going to show you each of these things right now. Let me just go here to the Internet.

After you set up the *Internet Explorer*, a little icon is placed out on your desktop, and I double click on that icon and you'll notice that it comes up to the MSN, obviously. This is MSN's presence on the Internet, and it comes up. There's a couple of things you should note here. We said that we wanted to make it very easy for people to use. A lot of people have never been to the Internet before.

Well, we have a tutorial on-line, a tutorial that you can get access to that teaches you about the Internet. We also have something here in the center which allows you to explore

from a single pane, and basically you're able, from this page, to search all of your search engines like your *Yahoo* and *InfoSeek* services, as well as 800 numbers, stock quotes, etc., etc., all from within this one window.

And there are a few other things that we've done to make it easy to use. Take a look at our toolbar up here; you'll notice that if I hover any one of these icons, we have something called "tool tips." These are the same things that you see in Microsoft applications today. You notice on the right-hand side we have Cut, Copy and Paste. Again, this is the same thing that you're seeing today in the rest of our applications.

Let me show you other things that we have. We have something called "favorites" in the Internet explorer. Favorites, if you're familiar with *Netscape*, are bookmarks. It's similar to that, where I can have all of my different favorite places that I go visit available to me at the click of a mouse. However, we do it in a way that's more "Windows 95centric." What I mean by that is that you can see that I can actually create a hierarchy of all of my different sites that I like to go to, so I can have all my educational sites in a particular folder, and my sports sites.

Let me just show you how easy it is to actually create one of these. I go to Open Favorites, and it will open up a favorites folder, this is — physically it's not a text file that your saving these bookmarks in, it's an actual file that sits out on your hard disk, and we have something called "shortcuts," and these icons here are shortcuts. If people aren't familiar with shortcuts in Windows 95 the notion of shortcuts is that you have pointers to particular files, pointers can also go to folders or whether local on your hard disk or out on the Network.

With the *Internet Explorer* what we've done is expand so that you can actually have pointers to different locations throughout the Web, so these are nothing more than shortcuts to different locations throughout the Web, and I can actually create a new folder here — and this is Steve's Favorites, and there it is.

So when I go back to the Favorites, you can see Steve's Favorites right there. Well what is the big deal about doing this? Let me just show you. What I can do here is — let's say I wanted to send this to a friend of mine, send a pointer to a location to a friend of mine. All I need to do is — and this is Microsoft exchange, since these are objects — all I need to do is click on this shortcut and paste it into the mail message. Then I just send it.

How many times have you wanted to just tell somebody to go look at something, and then you have to remember what the URL number is? A very difficult thing to do. I don't remember what the URL number is. Another great thing is that when this person receives it they just need to double click, and I'll show you that in a second.

A couple of other things that you should note about the *Internet Explorer*; what you can do here with the *Explorer* is... I can actually show you within the *Internet Explorer* how you can use the object technology. Let's say I had this graphic, and I wanted to grab that graphic. I just need to click on it and drag it onto my desktop. And you'll notice this, that what it does is it sticks a GIF out on my desktop. My GIF viewer is also the *Internet Explorer* in this case, and I double click on it and you can see up pops the GIF viewer and the GIF itself.

So you can see the object technology that we have built into *Internet Explorer*. Let me also show you how we're doing some innovation. I told you how we're supporting the industry standards, but we're also building on those industry standards to do some great things for content providers. Let me just double click on this shortcut... you'll notice a couple of things.

This is the Volcano Coffee Company, and the Volcano Coffee Company is a fictitious company, but what we've done here is we've put together our technology so that you can understand how it will work.

First of all, you notice how when I first came to the page we had background sounds, and you can preset these to run intermittently, one time, as much as you want. You also need to notice here in the center how we have something called an "in-line AVI," so we have digital

video support in-line in our browser. Also notice how we have something called “marquees” or scrolling text that comes across the screen, and you can again set these to any types of configuration that works with your particular content.

Besides these things, support for these in our Web browser, we also have support for Internet newsgroups, for [Cookies], and for VRML — if you’re familiar with the virtual reality markup language— for real audio, STT, Aware, and so this gives you a really quick overview of what the *Internet Explorer* and what it really means to content providers and what it can mean to users as they’re browsing the Internet.

You’re probably wondering how you can get a hold of it. A few ways. With Windows 95, [since] *Internet Explorer* ships on PCs that have been pre-installed with Windows 95, and this is a Windows 95-based product. You’ll see it on LAN-based machines, that are pre-installed with Windows 95, you’ll see it out on *Microsoft Plus for Windows 95*, which is an add-on package. You can go to our Web site, which is www.microsoft.com/windows, which will get you to the Windows portion of our Web site, and we have it available downloadable there as well.

We’re currently in beta for *Internet Explorer 2.0* and expect that to be released fully here within the next few weeks. My suggestion for you is that you may want to come by our booth and get a more in-depth demo of some of the features that I showed you here, and some of the other great Microsoft products.

So that’s basically it.

Jane Dysart: That’s the last of the speakers that we have from different companies here today. We invited some others to be here, but as we said earlier some of them are just too busy on the floor to pry anybody loose to come up here.

For example, in this section where we’ve been talking about some of the next generation tools that are out currently appearing, we’d hoped that we could get Netscape to come up and talk to you about the new things they’re doing; we’d hope to get the Sun to get up and talk about Java, which can be used with Netscape to give new capabilities that work on both your client systems and let you do more and better things.

And I thought I’d call attention and take a minute here to talk about the different forces that are at work here. On the one hand there’s a strong need for standardization. In order for all these vast different computers and different networks to talk to each other and share capabilities there has to be standards; and the Internet has long had its process of setting standards, which is a fairly slow deliberative process which seeks consensus and tries to get everybody to agree.

On the other hand we have some very strong forces at the work in the world today that don’t like slow deliberative processes; we’ve got lots of companies that are trying to get out there with the newest and best things, and make a difference and show differentiation between what they can show you and what the — which is kind of a contradiction with the process of everybody working the same way.

So we’ve got the market pressures pushing new things on us, and we’ve got the need for standardization perhaps trying to hold it back a bit, and the industry is trying to settle these things out. There’s an awful lot to be worked out in these areas.

Another trend we haven’t touched on very much here, though perhaps we’ve seen an aspect or two of it, is that we’ve talked about presenting content, and I see that as another thing which is very undeveloped at this point for the Internet. As it’s unfolding there’s the need for better communication between people.

The old Internet that we’ve experienced had very effective ways for communities of people to get together to talk, whether it’s newsgroups, whether it’s e-mail, whether it’s such things as chat on the line. Some of the those things aren’t scaling up very well. We’re going to

have to see, before we're through, some new forms of ways for communities to form and people to work together. That's a trend we're going to see, not in this Internet World, but I think we'll see both things develop in future Internet Worlds. It'll be interesting.

Another difference that we see in things is that everybody wants something new and unique, and yet people want to be able to do things as easily as possible, too. One of the things that we looked at and we saw very present on the floor is that there are a number of different Web-authoring tools out there; we didn't try and single out individual ones but we looked at a number of booths on the floor — and I will call your attention to them if your interested in how you can go about creating new and interesting Web sites, following standards and doing it with the least effort yourself. If you aren't somebody who has their own programming staff to create things to work with, we saw a Web-authoring booth, in addition to the ones you've heard here today, but we looked at all of those and they all had something interesting to look at.

If you're looking for your own capabilities and settling your own tools your going to use, they're all worth looking at. Is there anything anybody here would like to share, things you think we should have pointed out this morning and we didn't bring out to you, that you think it's important to say? Everybody's pooped.

And on that note, I'll let you go to lunch, and thank you.

HOT NEW TECHNOLOGIES VOICE OVER THE INTERNET: WHO DOES IT BEST? A SHOOT-OUT

MODERATORS

Jeremy Carl
Associate Editor, *WebWeek Magazine*
Andrew Kantor
Senior Editor, *Internet World Magazine*

SPEAKERS

Elon Ganor
VocalTec
Glen Hutton
Vice President, Sales & Marketing, *Web Phone*
Jeff Pulver
Publisher, *NetWatch*

Jeremy Carl: If you want to join the voice on the *Net Digest* or just the mailing list, what you do is you send e-mail to majordomo@pulver.com, leave the subject blank, then in the body you'd write: subscribe (space) von or von-digest, depending upon the frequency of the mail that you want to get. The mailing list itself tracks various vendors, not just VocalTec with CU-SeeMe and *Web Phone*. We actually have a representative sampling of the entire industry, not just two-way communication on the Net, but as well as broadcast audio on the Net as well. And you'll find on the list people who are users of the products, as well as the various developers and manufacturers.

Another very good resource on the Net for those of you who are sort of looking for information outside of what you might see or hear about today is Kevin Savetz, who is a sometime-writer for many of our publications. He maintains a voice on the Net Web page which is quite good. It's at www.northcoast.com/savetz/voice-faq.html. Let me do that again, it's www.northcoast.com/savetz/voice-faq.html.

This is the sort of thing that didn't even really exist, these sorts of products for all practical purposes, when we were at previous Internet Worlds. This is a very new technology. It's one that has excited a great number of people, and it's one that is very much in development; in fact many of the people who we were hoping would be with us still have their products in development.

But in any case, what I think we're going to do at this point is turn it over to, I think we'll start with Elon Ganor, who is the CEO of VocalTec, and he can tell you a little bit about his product. Then I'm going to have Glen come up, tell you a little bit about *Web Phone*, and we'll be taking questions from there. So without any further ado, Elon.

Elon Ganor: Hi everybody. I'm kind of surprised and happy to see so many people coming to see this subject. As about a year ago, I was cruising around the Silicon Valley and some other places, showing our technology, and as a matter of fact, we had been showing some of the vocal products. About two years ago we were doing basically the same thing, yet not on the Internet and some other systems; people didn't believe us at the time that this can happen. So for me, it's a very emotional moment, I must say, to see you all here.

The other emotional moment I had Monday morning when I saw the report on the *New York Times Business Section*, with the first serious analysis of what's really going on the Net. And there was a diagram there breaking up the different type of usage on the Net. The very lower one — which is still the lower one, but one day is not going to be so low on the chart —

was real-time video and real-time audio on the Net; and the number they quoted there was 1.3 million users out there. And I was kind of asking myself who those 1.3 million are, and what are the products that they're actually using.

And I couldn't help it to come to a conclusion that this one real-time video product out there that has been distributed for free for a long time, and has been quite known, and it's the CU-SeeMe product. Based on their numbers, their own company numbers, they are saying that there are 300,000 out there using CU-SeeMe. I'm not sure if those numbers are real or not, but that's the company quote. And then there was one more one million users out there using, I guess, the audio part, and I don't need to tell you which company is actually shipping a product out there since February. So that makes us happy, too.

I didn't really prepare any specific speech here because I was invited to be part of a shoot-out, and I'm sorry, but you kind of threw me here expecting me to give a speech — I was thinking I was going to give questions and answers, but I can tell you a little bit about VocalTec and a little bit about the *Internet Phone*, just offhand. You'll forgive me if I don't do it very well.

Anyway, the company is a young company. We've been five years in the market, since the end of '89. Our head office research and development center is in Israel, and Israel is a good place for technology. We have good engineers. We've been in the voice area, as our name implies, since day one, with VocalTec stemming from "vocal technologies." The company brought — and we made lots of mistakes, by the way, plenty of failures, I have to admit that — we brought five products to the marketplace. Each single one of them was first of its kind in the marketplace, so we do have the creative theme, and the leading edge-type engineers that can bring new, innovative products to the marketplace.

Yet I'm saying mistakes and failures because those products didn't hit it, and didn't make it big because they were either ahead of their time or not exactly what the customer really needed, and we've been listening for the last five years, very carefully all the time, trying to understand what the customer really wants and what the customer really needs. And the big opportunity came with *Internet Phone*.

Now, to list those products when talking about the CAT... That was Compact Audio Technology, a hardware product with our own chip design, our own [inaudible] in it, and that product was a [inaudible] product for portable computers. The beginning of '90, audio just became an issue in '91, and portable computers didn't have sound and soundcards, so we thought that would be a good idea. Everybody at the time was talking about audio annotation in documents, including Lotus corporation, WordPerfect, and others. That concept in general, didn't take off, and we didn't take off with it at the time. So that was kind of a failure — yet the product is a good product.

Then we brought Vocal [inaudible] as an application, as a software product. It is a voice communication product for your local area network, and it enables people to talk from one PC to another with the voicemail messages; [you can also] use it as a PA system so you can give up on those expensive PA systems installations and use your actual network to do that. And with that product, people would ask, "Why do I need to use my computer for voice communications as long as I have my phone?" And we had some good answers, but I guess they were too long; and in the market we're in, you have to give a 15 second speech, which we can easily do now for *Internet Phone*.

The next one was taking vocal [inaudible] into vocal [inaudible]. For awhile there it worked, and there was already a little more sexy, a little more interesting because a company with a dedicated switch a 56, 64, or T-1 between a London office and a New York office can use their PCs and their [inaudible] to communicate.

The immediate competitor to that would be a multiplexer that typically would cost around \$20,000 for that piece of hardware. And the major disadvantage, more than the money

issue, is the fact that it takes a fixed bandwidth. So if they have a 64K, 32 will be devoted for speech or voice, and the 32 others for data. That's not great, that's not very smart because you don't speak all the time with your London office. You do it when you want to do it. So you can use it for data more.

The vocal [inaudible] concept was a much better one, and I guess the time will still come that we'll see all those companies using the vocal [inaudible] concept, both for the [inaudible] and for the [inaudible], and actually this is still very interesting. So the time will come for those products as well.

It was a natural extension and a natural evolution to bring *Internet Phone* in then, so what you're seeing here is a company that is totally devoted to voice-processing on PCs and understanding the needs. We are market-driven on one hand, and we're trying to do the best to listen to our customers, and the Internet provides us an absolutely excellent place to be in order to be able to communicate with our consumers and our customers easily and quickly.

Internet Phone came to the market February 10th, and when we brought it to the marketplace a week later I knew life is never going to look the same for anyone at VocalTec. So I kind of started jogging to start with, because I said to myself "If I have to run the same kind of lifestyle that I have before, I'm going to get a heart attack soon." So I lost weight, and I'm jogging every day now and it's wonderful, and we have a very busy life and it really looks good.

One million users out there in eight months is not a simple task. We are being very aggressive in where we take this. The idea is really to make that a de facto standard as quick as possible, and the reason is very simple — unlike typical software products, which are divided... If you look at the normal distribution between competitors, you see a 60-50% split typically for different types of products, with 50-60% taken by one leading company, another 20-30% by number two, and 10% divided by 20, 30, or even more other competitors.

With an *Internet Phone* type product it's more difficult because it takes two for a tango. It's a bootstrap issue. If you have 70% of the market, or 60% of the market using one product, then the others are locked out from the real world. They just won't be able to talk to others. So if you have a cousin in Australia and he bought a new machine that provides him with a *Internet Phone*-type product, that will not be compatible with what everybody in the U.S. is using, you'll be just locked out.

And that's why we needed — we understood the market and the business, since we had the Vocal [inaudible] product two and a half years back, and we realized we had to take a very aggressive approach there. And that's exactly what we've been doing — we have a very strong OEM policy, and retail. We are in the retail through Ventana Communications, which was a very good deal, I think, for both VocalTec and Ventana because the numbers are exceeding the expectations. And we are basically in all major stores, so that's the retailer channel on the OEM side.

We have announced, up to now, about 20-something deals with major modem manufacturers, about 50% of the modem manufacturers. When you will go out there and buy a modem over the next few months, in 50% of the chances right now — and it will probably be higher numbers later on — you'll get an *Internet Phone* bundled with the modem you buy, because these guys realize that the modem is no longer just a data product, it's a voice product, too. And they are using and leveraging the fact that they can do something new because a modem is a modem is a modem, and they want to have nice, new things to be able to push their product.

Same applies with PC vendors. I'm not at liberty to discuss the names that we've signed deals with, but they are three among the major players out there that will ship their product sometime in the future with *Internet Phone* pre-loaded on their hard disk.

We had an announcement on Monday with America Online, the GNN service: Anybody from you guys that isn't GNN will get *Internet Phone* for free from GNN. PSI had announced on Monday evening the same thing. PSI will provide all the new customers coming in, or all the existing customers that request it, will get an *Internet Phone* for free. And that means that by mid next year we'll have more than seven and a half million users out there.

And I think the product speaks for itself, and since we cannot demonstrate it over here... I'm not trying to rob anybody, the idea is just that we have a booth down there and you are all welcome to come and just see it, play with it, and judge for yourself. And by the way, one last word, and that is the product is available as a free demo. You can download the product on the Net at vocaltec.com, and that's VocalTec without an "h," just vocaltec, www.vocaltec.com, and you can go and download a demo version that will enable you to communicate for 60 seconds or whatever your speaking time. On the average it's about two minutes, because if you speak to someone that probably takes some time, too. So it's a two-minute communication capability, and you can judge for yourself because it has to be put eventually to the test of the consumer. You need to decide whether the quality is good enough or not, and if you think that it's not good, don't pay us a penny. If you think it's good — then \$69, that's the risk you're taking. You can run as many sessions as you like with the demo of this thing. Thank you.

Jeremy Carl: The next speaker we're going to have is Glen Hutton, and he's the Vice President Of Marketing for the *Web Phone* product, which is done by the Internet Telephone Company out of Miami, Florida. I sort of admire them because they have come here with an alpha. Unfortunately, they thought they were going to be putting it up to test with everyone else's finished product, so they are hoping to have a final product out in the stores — when, about the end of the month? Close to the end of this month.

Actually, one thing I thought was humorous... I was talking with Rob Glaser, who is the CEO of Progressive Networks, another company, and they do real audio — not quite *Internet Telephone* — and he thought that perhaps they should be called, "The Miami Sound Machine." But we'll leave that to Glen to discuss, and he can tell you a little bit more about the *Web Phone*.

Glen Hutton: Thank you very much. First of all I'd like to say thanks for inviting us up here. We, unfortunately, are not able to demonstrate the product. I am as equally disappointed as VocalTec is, and I'm not rubbing it in, guys, I know you're still working on it. But it really would provide an excellent opportunity for those of you who are interested in voice/audio over the Internet to see the difference between the two products. There are some very distinct differences between our product and that of the VocalTec product.

To give you a background on our company, we're relatively young start-up. Myself, I've had two previous start-ups, so this will kind of be my third. I come from a telecommunications background and an audio background. I have a lot of experience in marketing, as well. We have chosen a slightly different path to present the product. You can download the product off our Home Page, which is www.itelco.com, and you'll be able to download our multimedia help system which is currently available. It's a very interesting help system. It's probably unlike of that which you've ever seen before.

The phone itself also is a very unique application that was up a little while ago; it's not there right now. Hopefully we'll be able to bring that back up again. The phone allows you to have the ability of four concurrent conversations. It's probably very much akin to the feature phone that you have on your desk at the office. You can take one call, place another call on hold, and within a 486 environment, you have the ability to do call-conferencing.

The alpha itself is a very stable product. We've had numerous hours of conversation, contiguous hours of conversation. The beta will be released this November 6th, I'm not sure what day that is. Friday, I believe it is, of next week. And you will have the opportunity to download the product and demo the software, very similar to what VocalTec offers you as far as a demonstration product.

There are a lot of other applications built into the phone in that it works over any TCP/IP network, so you're not necessarily tied into the product with the network. Additionally, you are not required to sit on an IRC channel waiting for somebody to ring you up. If you are looking to use a phone product for communication purposed, i.e. a business environment, you will not have to be forced to sit on an IRC channel accepting calls that are of non-interest to you. That's one of the concepts behind the product. You will also have the availability there to have yourself posted, so that if you do wish to communicate with other people and have chat, and just sort of shoot the breeze with somebody on the Net, you will also have the opportunity to do that, as well.

One of the other benefits of the product is that it doesn't require... There are some other products that are coming out on the market, two other companies which are not here today.

Jeremy Carl: One thing I should have probably made clear before is that there are a couple other products that are sort of out there. We did invite every single player with a product on the market, and some, including Mr. Hutton's company, that were not on the market; however, DigiPhone and NetPhone were rather evasive about sending someone here. It turned out the reason why — and this is actually going to be announced here for the first time today — is that DigiPhone is purchasing NetPhone. And I think this explains, perhaps, some of their reluctance to commit to sending separate representatives to the show. So I guess we'll see that evolving and perhaps some of our panelists will feel free to give their own opinions on these products. I'm sure they have them and you can feel free to query them about any of the audio on the Net products.

Glen Hutton: So anyway, as I was stating, basically with some of the other products that are out on the Internet, you need to know the IP address of the individual that you're trying to reach. I would assume, and I'm guessing, that was one of the initial reasons why VocalTec decided to go the way they did, and perhaps hopefully when we have a Q&A later VocalTec will be able to either: a) defend themselves, or b) clarify the statement that I made. I'm not trying to put any words in your mouth, so later on we'll have an opportunity to discuss that.

So the bottom line is that you don't have to sit on an IRC channel, and through a patent-pending mechanism that we have you will literally be able to use a person's e-mail address, and by punching in their e-mail address we'll make a connection for you. And for example, if you were on NETCOM you may have a dial-up IP, which changes dynamically depending on where you are. You may be in California one day, you may be in Florida the next day, it doesn't matter. Transparently, we are able to locate that individual if they're on the Net. So it makes it a very viable product in that you're not locked into sitting somewhere.

Additionally, the product also has voicemail built into it. And you can receive voicemail whether you are on-line, or off-line, and that is certainly a tremendous boom as far as voice on the Internet goes. This product was really very well thought out, and if I do say so myself, very well designed. The interface is just an incredibly beautiful interface. I've never really seen anything like it before. The various magazines, Byte magazine, which has an article coming out on our product in February, *Window Sources*, I mean the guys that have been doing the reviews have literally called me back and said, "You know I have never seen a product that looks like

this, nor have I seen a help system as interesting as this, and it really is a very interesting product.”

So anyway, without further boring you with the technical details, I guess, should we go to another session, or...

Jeremy Carl: Okay, all right.

Our final speaker before we get to a Q&A is Jeff Pulver, and he is the publisher of *Netwatch*, and he also runs the *Voice on the Net* digest. He can give you the relevant addresses for that. He's going to talk sort of generally about the evolution and the current state of audio and telephony on the Net, and then we'll get to questions for all of our panelists. I hope that doesn't intimidate you too much there, but Jeff, take it away.

Jeff Pulver: Thank you. And I do comment that I was not prepared to give a presentation; some of this will stream, but not necessarily coherently, and I apologize.

Just a little background. Can I see from the audience how many people in the audience today have tried a “voice on the net” product? Okay. How many of you have heard of using the Internet to actually talk to people? Okay. So it looks like there's a lot of people here who are aware of what's there, and some people have actually tried the technology.

I think, as we chart history, 1995 will be the year. One of the things that 1995 will be known as, besides O.J. and everything else, is really the year that streaming audio hit the Net in a big way. And as time has gone on, we've seen with the introduction of *Internet Phone*, and being able to communicate two-way really effectively on the Net; and the whole start-up of a culture which has been growing from there, to the broadcast industry, with the introduction of real audio, and being able to do on-demand broadcasting, and so on. It's really changed the way we look to the Net as far as functionality to us, and how the Net affects us as individuals.

Talking a little about from the personal side... my background, besides being involved in technology and finance and working on Wall Street, is I happen to be an amateur radio operator for 21 years. And I, you may not know this, but I like to talk, and I like to communicate, and I have this thing for like reaching out and talking to people around the world. I was the kind of person that used to stay up until two or three o'clock in the morning and try to get that rare station in Africa, or somebody in Southeast Asia, to say that I spoke to everybody. And for me, it was personally challenging. I could never justify why I did it, but I was doing that kind of stuff.

And when I first got *Internet Phone*, and one of the things you notice immediately with amateur radio, this [inaudible] propagation, you have to care about sunspots, you have to care about ionosphere conditions and all these wonderful technical things, but the fact is that people, whomever you spoke to, would fade in and out. If they ran a lot of power maybe you heard them clearly. With *Internet Phone*, you talk to somebody in the Philippines and it's as if I'm talking to you right now — it's clear as a bell. There are times when the conditions aren't so good, but you bear with it; and especially with my background, it's amazing.

And with the Internet, I've learned there is an analogy with ham radio. The state of the routers in the Net happens to be like my sunspots; and when [inaudible] goes down, I can hear it because I see all these people drop out, and it's really become a whole culture of a way for people to get involved and to communicate.

As far as what CU-SeeMe represented to me, I was on the CU-SeeMe list. I don't know if you people are familiar with CU-SeeMe? Beginning in February for the first two weeks, there was so much noise about CU-SeeMe I couldn't figure out what was. So right before the project was announced, I announced, on the CU-SeeMe list, “if you want to talk about CU-SeeMe, come here.” And what I had done is set up an CU-SeeMe mailing list as a way to divert traffic. I

had no idea that it really would affect what I did for the next nine months, as far as being involved with the technologies. But over time, the first few weeks of CU-SeeMe being introduced to the Net was kind of an interesting experience for everybody.

Could you imagine people talking to each other, and actually talking to strangers for no reason? What happens is, the way CU-SeeMe starts off is, unless you intentionally set up a conversation with somebody, what you have is you have a whole group of people there waiting to talk to perfect strangers — and it's kind of weird. Can you imagine being marketed to? It's like people don't like being called at their houses to be told about a new product, but I found a whole genre of people who are very excited to be called by somebody in New York. And over time that's really grown, and it was just a new experience for a lot of people.

And what happened early on with my involvement with the technology — some people associate me with VocalTec because I set up the CU-SeeMe mailing list — but the fact is because of what happened in February of this year was as CU-SeeMe was starting to get rolled out and starting to get popular, the EFNet got together. EFNet is a loose affiliation of — are people here familiar with IRC? Some people? So EFNet is a loose affiliation of corporate and non-corporate entities that really manage and host IRC servers.

And the first week of March of this year they decided to ban CU-SeeMe for no particular reason, and if I didn't have the mailing list as a way to communicate with users I would have never known myself what was going on. But as an individual who tried to make a difference — I happened to have a 56K line in to my house at the time — I decided to set up an IRC server and say: Hey, does this work? And it did. And as a way to combat what was happening with EFNet I set up a private IRC server and — I'll be brief, but what we did by setting up the IRC server is we were able to isolate the traffic for CU-SeeMe away from the public IRCs and into a whole private one, and really help to evolve a culture.

From that, within a week I announced that I convinced VocalTec to set up a server, and I'm happy to say today that there are now 16 private IRC servers running around the world, which run from Tokyo to Moscow to Great Neck, New York — all providing a facility to find people.

I then started getting involved on the culture side, because can you imagine, when you start talking to people you never knew before, all of a sudden you have friends. So I set up a user directory, which if you go to www.pulver.com/iphone, you'll find that there's a whole directory. Right now there are over 2,000 people listed. Yes?

M: [inaudible]

Jeff Pulver: www.pulver.com/iphone, and what's happening is that there are whole cultures of people that come by. If you fill out the guest book you get listed by occupation, by interests, by location; and if you're an attorney, or you're an accountant, or you're in aviation — you'd be amazed to see how many people there are from your profession. And then we have links to people's Home Pages, and this is not sponsored by anybody but myself. And I did it really as a way to provide a way to find out who's out there, so that the extent of your conversations with perfect strangers would give you a little depth and background. This way you can find out a little bit about Jeff Pulver, who he is, what he likes, so that when you're talking to someone on CU-SeeMe, you could actually scan the directory and get a feel, so that the conversation is more than, "Hi, I'm in New York. You sound pretty good. How's the weather?" And what's happening is that people have been commenting back that this is really helping to evolve the whole technologies.

The [inaudible] has seen not only CU-SeeMe, but certainly we've seen and heard about DigiPhone, and I prefer not to comment about that; and now we've seen announcements with

Web Phone . And what you'll find is that over time, one of the challenges to the industry is to find a standard. Because if you and I had cellular phones, and each of us had different models, it would be ridiculous, even though we had different manufacturers, that we can't all talk to each other. But what's happening as cyberspace and various technologies are evolving, is everyone needs to stand back and figure out who the standard is going to be, and then allow for it to be adopted by everybody; otherwise we're going to see before our own eyes and hear with our own ears is a cyberspace version of Tower of Babel. Because as people innovate on [inaudible], and people provide great technologies, as someone who's watching the industry go by you like to see everyone benefit from innovation but also still be able to communicate with each other.

Anyway, I don't want to ramble on. I do publish a magazine called *Netwatch*, It's www.pulver.com/netwatch. Every couple of weeks we take a look at organizations that are involved with enabling technologies on the Net; we track video, audio marketing and services. If you have a Web site that's interesting, and that you think should be covered, please send e-mail to me. It's jeff@pulver.com, and I'll be happy to take a look and let you know our feelings. And the *Voice on the Net* mailing list is a place where people from the industry have been to rant and rave sometimes; put out information about new content, new technologies; it's really a place just to, if you have questions — come by. It's a bunch of friendly, informative people, and it's really been a reflection of my experience on the Net today. Anyway, thank you.

Jeremy Carl: Our speech-shortening technologies are still working very well. We at least can threaten speakers if you still maybe can't get the network working. I'm now going to open it up to for questions, and I'll just take the gentleman here in front first.

M: [inaudible]

Jeremy Carl: Right. Actually, I'll let Glen start with that. Once again, in fairness to repeat, I should have probably said this for the DigiPhone/NetPhone. NetPhone is really the commercial product I'm aware of on the Mac side, although there is *PGP Phone*, which is done by the same people who do *Pretty Good Privacy*. That's sort of a beta that's not commercially supported at this point. So we did invite Mac people there, and just unfortunately, the one group was just sold, so... Glen?

Glen Hutton: Would it be good, maybe, if we stood up together so that we could address everyone as opposed to having to get up and down? Just because I assume you have a response, as well.

To answer your question...we are working on a Mac product currently, and I should have described that to you. The current platforms that the product is supported under are Windows 3.X, Windows NT, Windows 95, and OS/2. As far as the networks that we've tested it on, as I've stated, anything that runs on a TCP/IP network; we've tested it using it on the Microsoft stack, for the Microsoft Network, Trumpet Winsoft, Chameleon, all the various stacks that are out there for those of you who understand what I'm referring to. And hopefully that answers your question.

Elon Ganor: In our case, we have committed to release a Mac product by the end of the year. It'll be a cross-platform to the Windows product. We do support all the platforms that were mentioned except that we OS/2, and we are not about to bring an OS/2 product any time soon to the marketplace.

M: [inaudible]

Elon Ganor: No. All the other platforms, yes.

Jeremy Carl: Further questions? Right over there.

M: The issue will be being able to combine the audio with the next layer, which is obviously going to be some image or video. What's the prospect here? I hear [inaudible] is possible, how about the image portion?

Elon Ganor: I'll repeat the question. The question was about integrating audio and video. Obviously VocalTec looks at everything that has to do with communication, and it's our company policy to announce and ship, and not to put any vaporware out there, so we'll stay that way.

Glen Hutton: As far as our product goes, there is a part of the product which is an element called the "Web board." The Web board will provide initially — and I don't mean to mislead either, it will not be in the initial release of the product — but very shortly thereafter the Web board will be providing still images of an individual that you're talking to, etc. And ultimately, certainly, as I'm sure VocalTec has the same plans, to introduce a video-type conferencing sort of product.

Jeremy Carl: Just to give a slightly independent spin on things... if you do want to do video on that today, there are opportunities right now. People from the very beginning of have been using it, and I'm talking about Windows platforms right now, but there are, of course, platform versions available. For people who want to do CU-SeeMe, for example, although CU-SeeMe hasn't really had an effective voice channel, people have been using CU-SeeMe as the voice communicator, and other voice products as they're available today. It is effective.

As far as the way you see multimedia come to the Net, Real Audio announced a couple of days ago, *Real Audio 2.0*, and one of the enhancements which was significant was that they're adding a multimedia component so that when you set up the stream you can actually embed a URL, so you can get a multimedia effect like a slide show as things go on.

And then there's a company, an Israeli company, that came to the show called VDO, with *VDO-Live*; if you want to see 15 frames per second at 28.8, I think it is one of the hottest products at the show. I apologize, but as far as what got my attention at the show this year, it was this VDO product. At 15 frames per second at 28.8 it's sort of showing you a little bit about what the future is going to be; and how '95 is streaming audio, and '96 is going to be streaming video.

Before we take any more questions, I think Andrew Kantor entered. Do you have an announcement of some sort?

Andrew Kantor: Well, it's kind of a... we've got the connection up, and we've got the products loaded, we've got both *Internet Phone* and *Web Phone* loaded, but Mr. Murphy has once again reared his ugly head and now it seems the microphone may or may not be working. But as you all found out about five minutes ago, the speaker does work, so we can certainly show off the interfaces. We may not be able to talk, but we can certainly listen, and we can see maybe the microphone will work. So if you want to finish up, this should be ready and we can try, we can show off your interfaces.

Jeremy Carl: We'll go ahead and I guess let you guys do that now. If you want to get toward your computers, or however you guys want to do that, and we'll attempt to actually communicate here for a second.

M: [inaudible]

Jeremy Carl: That's VDO, they're actually distributing. I mean, they're actually displaying their ways at the booth, 10 to 15 frames per second video.

[Panel]: Do you want to give the Webs to the [inaudible] part?

[Panel]: It's www.vdolive.com, also if you go to www.iworld.com you'll find references to them there, as well.

Andrew Kantor: Microphone is not working. Oh boy.

Jeremy Carl: Oh, well. In the meantime, while we play around with the microphone... further questions? Yes, the gentleman in the red.

M: [inaudible]

Glen Hutton: Yeah, there was an issue a while ago regarding that and Quarterdeck. That has since been rectified. Quarterdeck was claiming that they had rights to the trademark for *Web Phone*. We also, the Internet Telephone Company, also claimed to have rights, and at this point, Quarterdeck has backed down. So I assume that they have acknowledged our rights to the name *Web Phone*.

[Panel]: Was it just the name or was it the same product?

Glen Hutton: No, it was the name, it was not the same product. Their product is a completely different product; they have continually announced that they're probably just going to be forthcoming. I haven't seen anything yet.

[Panel]: *Web Phone* was, in fact, invited to this, [inaudible] *Web Phone* is right here. Isn't there *Web Talk* now?

[Panel]: I think it's called *Web Talk*, and that's what they're going to refer to it as.

Jeremy Carl: Web-Talk, from Quarterdeck, was invited repeatedly, they even have a large ad touting their services in some of their magazines, so I can only assume that they are actually forthcoming at some point, but they declined to participate saying that their product was not quite ready. And that's really all we can say about Quarterdeck at this point. If there's a Quarterdeck representative here who would like to clear up that, then they can, but as far as I know, it should be out imminently, but they declined to participate.

M: [inaudible]

Jeremy Carl: I'm sorry, I did this earlier, but perhaps everybody didn't hear me. Yes, Camelot, DigiPhone was invited and because they had purchased NetPhone and were sort of in the

process of doing that, in fact evidently it's gone out on the wire today. NetPhone being an *Internet Phone* product for the Macintosh, both they and NetPhone, who were invited, were sort of being a little bit cagey about sending a representative. I guess they didn't want to have two representatives, and they also didn't really want to clue us in as to what was going on with their company. So they declined to send a representative here, as far as I know.

M: [inaudible]

Elon Ganor: Actually, the way we see it at VocalTec, being a voice processing company for five years, is other companies jumping on a bandwagon after us identifying a market before them. I will urge all of you to go to Camelot and find out in how many businesses they have been over the last twelve months, starting from oil and gas drilling; and building up a chain of CD-ROM stores; they've been keeping on promising that they'll be in 200 franchise stores — there's still one, in Dallas — and some other businesses. So you have to use your own judgment.

Now, I got a phone call last week from the president of [inaudible], which was the company that actually acquired the product, just to make things clear here; and the company that acquired the NetPhone product was [inaudible] to start with, from the Electric Magic, which are very nice guys out of San Francisco that have done a nice product for the Net platform — not a very professional product in our opinion, but pretty nice for the Mac. And then they wanted us to bid against Camelot, and I just refused to bid because we are going to bring our own product, and they said these guys are going to take this product.

[Panel]: How much did they pay?

Elon Ganor: This is not something, I think, that would be ethical. I know how much they paid, and I said, "Good for them, let them buy it." Now I just want to wait and see how they're going to do the cross-platform issue, because this is not going to, probably initially, to work together. How many of you tried to use DigiPhone? How many of you actually tried to use the product? Nobody. Okay. I don't want to comment. I would urge you to try and buy it, it's worth the \$49 just to see the experience.

Jeff Pulver: Just a comment briefly about that. I actually did a review, which I haven't published, it's going to be available this week on *Netwatch*, where we compared CU-SeeMe versus DigiPhone to try and set the record straight. And after I bought the product, I actually stopped doing the review because I felt that if I was going to continue with the review I would have authenticated the fact that this was a product that was quality to buy. I felt very uncomfortable, but we did it anyway.

And we looked at it, we compared the two, and certainly if you go to the stores and you buy today, try it out; but our reaction, it was myself and three others, and we bought a product and it GPF'd immediately as soon as we took it out of the box, so it left me with an uncomfortable warm-and-fuzzy as far as functionality goes. But I'm sure it works for some people.

I managed, after six hours of phone conversations, to get it to work, but I was never able to get it to work with somebody who I didn't set up a schedule with first on the telephone to confirm, to find out whether they were available or not. But you can certainly form your own conclusions.

Andrew Kantor: If you can hear me now, and I guess you can, it means we are up and running. Who wants to go first? Do you want to arm wrestle or draw lots, or...?

Jeremy Carl: VocalTec can go first.

Glen Hutton: I insist, really. You guys are the leaders — go ahead.

Elon Ganor: They want us to be first, and there's a very good reason for that. They've been watching what we're doing for the last eight months, and I want to tell you something... VocalTec, over the last eight months, has released three products to the marketplace [inaudible]. At the time, now only about 14. They may well understand what it means to bring three products, and when I say three products, February 10th, we had *Internet Phone*, on June 5th we announced [inaudible] and we were shipping the same day. And September 25th we announced and shipped Internet [inaudible], which is a competitor to real audio.

Obviously you may well understand that this product is Version 1.0, and it's been out there eight months with one million users. So you have the basic features. [Inaudible] wants to show his product because it probably has more features, but we [inaudible]. Obviously they did. Other products coming and those are not going to have them, in the very late future, but rather in the near future. So you have to keep that in mind.

M: [inaudible]

Jeremy Carl: While we're waiting through this uncomfortable laughter, if there are any further questions... Yes, the gentleman right there.

M: Maybe you already covered it, and I came in late, but what about AT&T? Where do they sit? What's the deal? I mean, don't they have, aren't they concerned about this?

Elon Ganor: Let me explain, do you mind? The way we see it... this question has kept coming up over the last eight months all the time, and there are very basic things we need to understand. There are various market segments here we're talking. It's a very big business — voice is going to be very big business. It is already, for the telecom guys, and on the Net, it's something different.

Let's take, for example, what Jeff here was describing, the ham radio type. Ham radio, in order to become a hobby you need to go through some tests that you have to be qualified by the FCC, that's one major barrier. And you have to spend a few thousands of dollars on equipment. And after jumping those two barriers, you end up with one million ham radio hobbyists worldwide. Now take those two barriers away, and how many people would love to, he said, "I don't know why I do it, but I do it. I just enjoy chit-chatting with people all over the world." And I guess it'll be more than one million people that would love to do that, and actually *Internet Phone* proves that fact, and without the barrier.

So the market for those guys are maybe five million, maybe twenty million, I don't know. I have no idea, because it's hard to find out, and just jumping and testing it, and it seems that many, many people would love to do that. So that's happening. And that's one market — you don't do that on the phone — never with an AT&T connection. You don't pick up the phone, call someone and say, "Hey, how are you? How's the weather there?" because he's going to hang up on you, believe me.

My mother has a sister in Australia, and she calls her five, six, seven times a year to wish her a happy holiday, happy birthday, happy something. And she's watching her watch, and she's counting, and she doesn't do it long because it's about \$4 a minute. And so she just doesn't use it... and that's a major thing. That's a very important thing. Now imagine if she can actually start

talking to her sister, chit-chatting and gossiping, even though the quality of communication is not the same.

One thing I have to make clear here. This is not a phone-quality. It's not the phone. It's not replacing the phone, and everybody, they're telling you that this is replacing the phone and that is just not the truth. It has delays, and the delays have nothing to do with the quality of engineers we have — it has to do with the Net. It will improve; this is ground-level. We just established ground-level. So we have a sort of between half a second to two second delay on international calls, and it depends on your access provider, on the type of PC you're using, on the type of modem you're using, the connection you have. There are many, many factors. You have to do it seriously. So that's another market that today is not being at all addressed by any of the phone companies. Just give them the capability of [inaudible] for two hours on a long distance with a minimal cost.

Even though the quality of communications, there's a cost/performance issue. Then we're looking at the competition where we're seeing already small businesses and medium-sized, and we have some things in the pipeline for them. In the corporate environment this product will be able to either [inaudible] or do other things than just voice communication.

And as a matter of fact we came from that angle, and we decided to jump into the consumer thing and the whole IRC that you're seeing, some people will attack on that. We see that as a tremendous advantage. Because, mind you, there is a bootstrap issue.

One of the frustrations people have is that when they're trying to use DigiPhone, when they finally, after six hours, as Jeff said, succeed in installing it, they have nobody to talk to. Then you need to set up somebody on the other side to talk to. And here we're giving you the opportunity to meet other people and start communicating with them; and they are divided by interest groups, that address, the Internet community, the one that actually pushes the Internet to what it is today.

By the way, you don't have to be on all those channels and [inaudible] has a private company channel, and we are not on all the other channels, and you don't need to meet all those people. That's one mistake Glen made here. But you can be on your own company. We have a VocalTec private channel and that's it.

Jeremy Carl: Glen's going to, I think, briefly answer that, and then evidently we do have the network back up and running. Glen will defer for the time being for the 3.5 seconds we'll probably have this network up.

M: My name is [inaudible], Technical Director of VocalTec and one of the company's founders. And this is the [inaudible] we interface off the *Internet Phone*. What we can see here is ten quick-dial buttons that you can use for users that you are frequently calling. So you can set those to anyone from your business family, or just friends that you're frequently talking to. We have a toolbar here. I'll press the call button and what I'm getting is a list of users that are currently on-line on the Internet and using the *Internet Phone*. We have a network of servers that we call the *Internet Phone* servers because they are dedicated *Internet Phone* servers all over the world. We have them in Europe, we have them in Russia, of course a lot of them in the U.S., we have them in Japan — all over the world.

And I kind of think that I lost the Internet connection again here. So let's do a dry run here.

Basically here, if you're pressing the refresh button and you have an Internet connection, you're getting a long list of topics that are currently available. Those topics can be either public topics or private topics. Public topics are topics that people are creating in order for other people to join them and talk about subjects they like. We have a lot of topics for people that

are only speaking Portuguese, or Chinese. We have topics for Russia, Israel. We have topics about computers. One of the first topics that was created was by a guy called Paul who created a topic to sell his boat. So he put the type of the boat, and some details in the topic, and people were joining the topic in order to get the boat from him. At least in each topic like this, that we can't see right now, you have at least one person that created it. If all the people from that topic are quitting the topic, the topic will disappear. So those are public topics that anybody can join.

If you want to create a topic for your own family or your own business, you can create a private topic which is not listed in the list of topics. Private topics are topics that are not listed in the main list of topics. And those topics are created in order to have a telephone call which is not listed in the global telephone directory because with the *Internet Phone*, it's very easy to call anybody that is on-line. So maybe to give a personal example, we have five computers in my family, and we have a private topic of our own, and every day we have a schedule that everybody is talking together. My sister lives in Long Island. I'm living in New Jersey. My family lives in Israel. And we're all joining up for a conversation almost every day.

For the business, we have a private topic that we're having almost daily meetings in VocalTec because we have our research and development facilities in Israel, and...

Here is the Internet [inaudible] topic and we can see some people that joined it. We can see people on the show floor. We have a few people of our own, and a few other people. But let me search randomly for a user that I can talk to which is not on the show floor.

Hello, I need a volume for the computer. Hold on for a sec, I have to set the volume level here on the computer probably. I'm already connected to user, but unfortunately... No? No.

Matt, can you try and talk to us? He is talking, but still no audio.

Hi, my name is [inaudible], and I'm doing a presentation in a computer show called the Internet World in Boston.

Hi, can you please tell us where you're talking from and how you connected to the Internet?

M: [inaudible]

Elon Ganor: The sound quality here is not really great, so I'll try and set...

Matt, can you tell us for how long are you using the *Internet Phone* and who you spoke to when using it?

[Matt]: [inaudible]

Elon Ganor: Okay, great. And what about the quality of the calls? We have a lot of people that are not actually listening to a great quality right now because we have a problem with the amplified system, but can you, do you have any comments about the quality of the calls that you had world-wide?

[Matt]: [inaudible]

M: I see. Okay. Thank you very much, Matt. We'll try and have one more conversation, so thanks a lot and bye-bye for now.

Okay. It's not the greatest demonstration because the audio quality over the PA system is not great, but you can see that we have continuous flow of audio from the computer, and the conversation is fluent. Let's see if we can talk to someone else.

[Panel]: Let's actually, I'd like to let Glen have a chance to demo his product, and right before then I'd also like...Elon would like to say something.

Elon Ganor: Yeah, I'd like to mention, and to specify a few words about quality and the quality of voice communication. It has a lot of factors. One single factor is probably the most important affecting the quality of the voice you are listening to is the microphone on the other side. Most people are buying a multimedia machine. They don't have a microphone at all, or they get a very cheap \$2 type microphone; and this will affect tremendously the quality of the receiving end.

The other thing is, obviously, the type of audio board you're using. If you're using an 8-bit old 91-type audio board, the quality is real bad. And then if you go for 16-bit or 32-bit type board, the quality improves very much. This will affect any product. It doesn't matter whether it's *Internet Phone* or others.

Then the access provider has a lot to do with it. You see a lot of Internet access providers are "ma and pa" type operations in a garage, having a T-1, and then they start selling Internet accounts to their neighborhood. And if they do it for 20 people, there is a lot of bandwidth available — there is no problem. This product takes about 7.7KB on the compression side, which is really not a lot. It's about half of a 14.4 modem, and that's why it works well with a 14.4.

On the other hand, if they are overselling, if that particular access provider is overselling his services to a couple of thousand people on a T-1, then obviously you get, when you're running a browser, the graphic interface will appear slower — you are willing to tolerate that. But with voice it will start being choppy, and there is nothing you can do about that. So our recommendation is to go only with the big, good guys that provide good access. And now we start seeing companies like PSI that just announced on Monday more bandwidth, and more secure type of capabilities.

[Panel]: We have a *Web Phone* hopefully ready here, and we're going to give it a demo.

Glen Hutton: Just so I can let you know, this is our alpha version. If, unfortunately, if we were like three days later, we would have the beta version ready to roll. And let me restate that position. The beta version, the reason why we are not able to bring a beta version to the show, is because obviously we have a lot of — as you can see from the user interface — there are a lot of things that have to be hooked in. The audio engine is all there, we just need to finish the final hooking-in of these images into the application. And I'll explain our product to you in just a moment, but in the interim let's try and make a call so we can get this puppy done and over with here. And here we go...

Andrew Kantor: Who are you calling?

Glen Hutton: I'm calling my office.

Andrew Kantor: You put in an IP address?

Glen Hutton: Yeah.

Andrew Kantor: So you're using an IP address like a phone number.

Glen Hutton: Correct.

Andrew Kantor: What about dynamic IP addresses?

Glen Hutton: Dynamic it will handle.

Andrew Kantor: Is it still ringing?

Glen Hutton: Yeah, it should be. I'll try again.

We have other people to connect to if this connection doesn't work for whatever reason. What network are we on?

Andrew Kantor: IBM's.

Glen Hutton: IBM's network?

Let me put that one on hold. What I'm doing now is I'm actually placing that line on hold, and I'm going to now dial another number.

[Phone Machine]: On hold...

Andrew Kantor: Oh, you've got to be kidding.

Glen Hutton: Yeah, the phone actually enunciates everything. There's a lot of, for lack of a better term, there's a lot of — I don't want to say it. There's a... it's a sexy application, okay? There's a lot of bells and whistles put into this. The product has been very well-tuned and very well-designed.

Okay, let's try. This is a connection to Boca, if we're still up... Hello, Steve? Hello. Steve, buddy, how are you doing, man?

[Steve]: Glen, are you there?

Glen Hutton: Yeah, I am Steve, can you hear me? Yes, Steve. Steve, hello? All right, let me try this one more time, let me disconnect.

[Phone Machine]: On hold. On hold.

Glen Hutton: Now what's really occurring here is Steve is actually placing me on hold, and that's why this is being enunciated.

Andrew Kantor: Is the microphone live or...

Glen Hutton: Yeah, we may be over-intenuating with all the background here.

Hello? Steve, all right, let me put him on hold. Whoops.

Anyway, one of the things that I wanted to show, obviously, is the audio quality, and I think in all fairness, just to prove my point, we should allow VocalTec... I would like to invite VocalTec actually to redo the conversation. What I did was reconfigure the board so it sounds a little better for you guys.

Andrew Kantor: Let them try and demo it at least.

Glen Hutton: Steve? We must be getting feedback from something.

[Steve]: Glen?

Glen Hutton: Yes, Steve.

[Steve]: Yes sir, you had a little bit of background noise in the room there that was keeping your mike open, but I hear you fine.

Glen Hutton: Yeah, I know. I apologize for that. Just setting up some of the parameters. How is everything in Miami? All right?

[Steve]: Everything is just wonderful.

Glen Hutton: Beautiful. You're coming through loud and clear, by the way.

[Steve]: That's because I'm using the telephone product that I got in the mail today.

Glen Hutton: That's very good. It wasn't called the *Web Phone*, was it?

[Steve]: No, no, it's called the *Sound Exchange*, and it's from a company out in South Dakota.

Glen Hutton: Yeah... You're a little slow today Steve. That's okay, no problem.

Anyway, you were talking to, I don't know, maybe about 125, maybe 200 people here, so do you want to say hello to everybody?

[Steve]: Hi there guys, I didn't realize I had an audience, but my name is Steve, and I'm down here in Miami. We're talking on the *Web Phone*.

Glen Hutton: How is Shane doing? Is he hanging around?

[Steve]: Shane is being a trooper. He actually said he wanted to talk to you at the show, and for me to get your address and I'll forward it to him.

Glen Hutton: Okay. You have the IP, so why don't you do me a quick favor and call him on the other line? Put me on hold, call him and have him give me a call. Will you please?

[Steve]: Will do — no problem.

Glen Hutton: Thank you.

Andrew Kantor: Okay. I've got a couple of questions while we're waiting for this. I want to talk about the interface because let's assume, as we'll see when VocalTec tries their product again in a minute, that the quality of the phone calls is about the same, with the setting set properly. With VocalTec's *Internet Phone* you log into a special IRC-like channel, get a list of users currently waiting, and then connect to one of those users. Is that right?

Elon Ganor: Right.

Andrew Kantor: And then when I connect, if I feel like chatting with someone, I'm going to be logged into this channel, my name will be listed with the others, and then if I want my friend Eric to call me he'll look at my name, see that I'm on the list, and he'll be able to call. So we both have to kind of arrange to be on-line. Meanwhile, other people can call me as well?

Elon Ganor: [inaudible]

Andrew Kantor: Other people may call me, and I'll see that it's not who I'm waiting for, and I can tell them, "Sorry I don't want to talk to you." Which seems to be fine if my name is Andrew, but tough if my name is, say, Tonya. Because I'm going to get more calls that way. So we're going to both arrange to be on a channel or be on a topic. Can he call me, and can I be listed there, or can I not be listed there, but still be waiting to receive a call? Like I'll say I'll be on-line at 2:30, call me. Can he do that? And without having anyone else know that I'm there?

Elon Ganor: Well, you need to put a nickname because you need to be able to click on a name in order to connect to, but you don't need to put all your information. You decide whatever you want to put there.

Andrew Kantor: Okay. But people are going to see me on the list. It's possible I'll get other calls. Okay, I can have a private channel. Now with *Web Phone*...

Glen Hutton: Excuse me, I have a call coming in. Just a moment. I don't mean to interrupt the show. Hello?

[Shane]: Yeah, Glen, this is Shane. How are you doing, man?

Glen Hutton: I'm doing okay, buddy. What's going on?

Andrew Kantor: How much has he had to drink today?

[Shane]: We're trying to figure out how to replace or turn off the VGA card that's in this NEC-ready computer, and replace it with an [inaudible] graphics, and there's nothing in the user manual about it.

Glen Hutton: Well, I'll tell you what, Shane, right now you're speaking before about 250 people, so we can discuss the technical problems later, perhaps.

[Shane]: Well, if there's somebody from NEC there, tell them that there's nothing in this user's manual how to disable the damned VGA.

Glen Hutton: You got a laugh, buddy.

[Shane]: By the way, there's something else — their video driver for Windows 95 has a bug.

Glen Hutton: Hopefully there's nobody here from NEC. Didn't we have a deal that we were cutting with them? I forget now.

[Shane]: Actually no, that's the one computer manufacturer I didn't talk to yet.

Andrew Kantor: Okay. Okay. Although we appreciate NEC's troubles, we do want to let VocalTec show off with a little better connection. But I want to ask you some questions about your interface.

Glen Hutton: Are we going to do that while we have Shane on the line, or do you want to discontinue the conversation?

Andrew Kantor: Let VocalTec connect real quick, and before they go, I want to ask you some questions while they're setting up.

Glen Hutton: Okay. Shane, we're going to blow out here. Thanks very much and I appreciate the call. I'll give you a call in a little bit.

[Shane]: You're going to hang up on me?

Glen Hutton: Yes Shane, I have to hang up on you, buddy.

Andrew Kantor: Now with your interface, as we saw with VocalTec's, the list of the users on a particular channel...

Glen Hutton: Shane, thanks a lot, I'll talk to you later, bye. Shane? Shane, you can't call any more, good-bye.

Andrew Kantor: Now with VocalTec's we see we have the channels, and you look on the channel, and you see who's there, and if the person you want to speak to is there then you can speak to them. With *Web Phone*, how does that work if I'm dialing an IP address? Or how do I, if I want to get in touch with someone, how do I do that?

Glen Hutton: To answer the question... regarding the alpha version that you're seeing here, it only allows point-to-point communication through an IP address. This product has basically been released to various hardware-level manufacturers. VocalTec has discussed their product being bundled with a lot of other computer peripheral products, etc. We also have similar deals, some of which many of you will be surprised and probably so will VocalTec, but that's okay. The bottom line is that we, for the alpha version, did not require the ability to use the connection server. On the 6th of November, when you'll be able to download the beta version, all you will need to know is the person's e-mail address. You will not be required to have an IP address to speak to somebody.

Andrew Kantor: So as I was asking you before...what about people who have dynamic IP addresses? How is it connecting? It's just going to go to the IP address?

Glen Hutton: Right.

Andrew Kantor: Find that person...

Glen Hutton: The magic is all performed by us. All we need is your e-mail address and we instantly find you.

Andrew Kantor: Okay. VocalTec is ready. Let's see if we can talk to someone.

Elon Ganor: We lost the connection. We lost the Internet connection again.

Glen Hutton: Now if I may point out...it seems that every time we use *Internet Phone*, we lose this connection. Is something going on? Is it you, or is it just a coincidence?

Elon Ganor: It's not us, believe me.

Glen Hutton: Okay. It's not you.

Jeremy Carl: Question back there while we're waiting.

M: [inaudible]

Andrew Kantor: How much bandwidth do either of these products require? What kind of modem do you need? Do both people need to have high-speed connections?

Glen Hutton: The minimum required for our product — and VocalTec, in that respect, the minimum requirements are very similar — a 14.4 modem, and correct me if I'm wrong, any 486. Okay, likewise with us as well; and a connection to the Net and a multimedia compatible sound card.

By the way, VocalTec also has mentioned the fact that their product is full-duplex. I will go on record stating our product is also full-duplex, as well, for those of you where that is a concern.

Andrew Kantor: Something about full-duplex. Full-duplex requires a full-duplex modem, which is not something you just run out and buy that easily.

Glen Hutton: Audio card.

Andrew Kantor: I'm sorry. Full-duplex audio card, which is not something that you run out and you don't buy as easily as you...

[Scott]: Hi, how are you doing? This is Scott from Internet World. How are you?

Elon Ganor: Hi Scott. It's Elon from Internet World also. I'm here demonstrating the *Internet Phone* before a very large group of people.

[Scott]: Great. We also have here about 20 people, and giving a demonstration of the *Internet Phone*, so where exactly are you anyway?

Elon Ganor: Okay. I'll try and call someone else also. If you have anything else to say to me, please do.

Guess not.

Andrew Kantor: I want to say about full-duplex... if you don't have a full-duplex sound card, you can't do this. *Soundblaster 16s*, the normal cards that come with multimedia machines, are not full-duplex sound cards. There are a few of them out there, but we have a *Soundblaster 16* right now in this machine. We cannot do full-duplex.

There's a big controversy going on supposedly right now in beta, at Creative Labs — and if there's anyone here from Creative, come see me afterwards. But we're all waiting for the driver to be available. I've gotten private e-mail saying it's actually available, and once the driver is downloaded your SP-16 will work full-duplex. Okay. So real soon now it's going to be full-duplex, but the point I wanted to make is — it's not like you're going to say, "Oh, I've got a fairly new sound card, a *Soundblaster*, it's going to work just fine." Not necessarily; in fact, chances are you're not going to be able to do full-duplex without either this driver that's coming out or a completely different sound card. One of the things... when we were preparing for this, we wanted to do full-duplex, but we couldn't find a full-duplex sound card. Yes?

M: [inaudible]

Andrew Kantor: How do you know who's on-line in *Web Phone* ? We'll get back to that in a second.

Glen Hutton: How do you know on *Web Phone* ? *Web Phone* has a built-in user directory. There are two levels of directory. There is a directory system which resides on your machine, sort of like an address book. And then there is a connection server, which is really the ITTEL WorldWide Web directory listing. And so you can literally go to that and search for an individual. It's interfaced directly into the phone, that sort of liquid crystal display that you saw up on the screen allows you.

If we have time, I'll quickly run through some of the applications and some of the interface modules of the phone. You literally can do queries and sorts, things of that nature, to find out an individual's name or address.

Andrew Kantor: Yes sir.

M: [inaudible]

Andrew Kantor: How much bandwidth does *Web Phone* use? CU-SeeMe says they use 7.7 KBs per second? What does *Web Phone* use?

Glen Hutton: The sampling rate — now this is very confusing. There are really several elements in this. It has to do with the bit resolution of the audio file, and there is also sampling rates, and there is also the throughput of the audio file. We sample at approximately 8,000 a second. The throughput is roughly 1.1K per second for audio. Yes?

M: [inaudible]

Glen Hutton: Okay. Conference calling is only available because of the amount of overhead required to do conference calling, it's only on a 586 machine. It's not so much decompression that is the problem, it's compression that becomes the problem, and so a 486 just does not have the guts to do it. That's the bottom line. Go ahead.

Elon Ganor: We don't provide that capability at this version.

Andrew Kantor: So neither of you provide conferencing, three-way calling, not yet. With a Pentium or 586 you can. You both do re-dialing, you have the buttons, you have the re-dial function. Will *Internet Phone* allow calling a specific person the same way without having people

listed on a channel? Is that something that's coming out? I want to call somebody, and I know his or her e-mail address, or IP address...

Elon Ganor: The product that was released in beginning in '94, [inaudible] was doing exactly that at that time. So that's something that is... the name server is something to solve a problem that exists. So calling someone with his IP address is easy thing to have, and we have that in a former product. So in the future you'll see that.

Andrew Kantor: Okay. VocalTec is going to try another quick call. It seems, at a first glance, that VocalTec is kind of like almost a CB radio, or you join a channel, you see who's there. It's like IRC, but with voice. You join a channel that is used there, and get into a private chat with them that way. Whereas *Web Phone* is more — dial an individual user from your own personal list, and they are waiting for your call, and there's not a public list. Is that not correct?

Elon Ganor: Well, that's not exactly correct because the way we are...

[M]: Hi, can you hear me?

Elon Ganor: Can you please tell us where are you located and how you are connected to the Internet?

[M]: Yes, I am located in VocalTec offices in [inaudible], it's near Tel Aviv in Israel. And we are connected through a direct connection to our service provider in the 64KB.

Elon Ganor: Okay, great. Thanks a lot. People here wanted to hear the sound quality of the *Internet Phone*, so that's why I called you.

[M]: Where is the show?

Elon Ganor: We are currently at the show and we have about 250 people listening to us.

[M]: Oh, in what country, I meant?

Elon Ganor: Okay. I'm sorry. In Boston, Massachusetts.

[M]: [inaudible]

Elon Ganor: Okay. Hold on for a second.

What you can see is a 400 millisecond delay in the communication with Israel. Leo, if you can show the VT band channel. We have a company channel, so when I check into a hotel in San Francisco, I get on-line with my computer to get my e-mail, and then the second thing I do, I run CU-SeeMe, and I see who's on-line from VocalTec in New Jersey, Israel, and if someone of say [inaudible] V.P. Of Marketing is in Stockholm at the time we can all join in so it's kind of a community which is internal office, internal corporate communication tool. And that's something one has to understand. It's enhanced with one click — the capability of us talking to each other.

Andrew Kantor: Something Glen just mentioned... do you have a hold or a mute button that you can tell them to hold on?

Glen Hutton: No.

Andrew Kantor: No. Okay. Features that I'm sure will be worked out soon. We have to wrap us this session in a couple of minutes, so why don't we just chat with him for another minute? I'd like *Web Phone* to get another shot at chatting, so we kind of equal that out. Yes, question.

M: [inaudible]

Andrew Kantor: Are standards being addressed? If you're using *Internet Phone*, you cannot call someone on *Web Phone*. If you're using *Web Phone*, you can't call, you have to be using... It's kind of like Chat, different Chat systems over the Net, if you're using one you can't necessarily use another. So there is no standard. You look excited.

M: [inaudible]

Andrew Kantor: Does either product offer any kind of encryption?

Glen Hutton: Not at this point. VocalTec, obviously, is going to have something to say about that, too. Again, one of the problems is when you start to induce Pretty Good Privacy, there are legal issues outside of the United States, and there are also some problems as far as the amount of overhead required to encrypt a signal further.

Jeremy Carl: Let VocalTec answer.

Elon Ganor: Well, the issue of privacy over digital-type communication is less severe than people tend to think it is. The product has compression, other algorithms to do reconstruction of lost packets, the delay-handling mechanism. In order to be able to tap on that, you need to do a whole reverse engineering of the software. It's pretty complicated. I would say it's a whole form of encryption, really. And actually tapping an irregular form connection is, by far, easier than doing it to an CU-SeeMe-type communication. In the future we'll be offering more specific encryption coding.

Andrew Kantor: Actually, we're going to let *Web Phone* connect one more time, and then we're going to have to close the session down, but we invite everyone to stay after. I'm sure they will be eager, both VocalTec and *Web Phone*, to answer your questions. And *Web Phone* is just going to do a last demonstration here.

Elon Ganor: Thank you. I'm going to hang up now. Bye-bye for now.

Glen Hutton: Who do you guys want to talk to? Do you want to talk to Steve or Shane?

M: [inaudible]

Andrew Kantor: Do either of the products do any kind of voicemail?

Glen Hutton: Yeah, our release that's coming out on Wednesday, or on the 7th, will have, does have voicemail built into it. And that is whether you are on- or off-line.

Andrew Kantor: So you just have to have the program running? And if you're not there? And if you don't answer it it'll just take voicemail?

Glen Hutton: That's correct. It'll allow you to leave a voicemail message. And also too, we obviously don't have the time to fully demonstrate it. I invite all of you, at this point, to, if you have access to the Net, go to www.itelco.com and download the multimedia help system. That will explain to you everything. It is, again, ten times more informative than I have time to provide you with information.

M: I want to ask VocalTec... do you plan to offer any kind of voicemail?

Elon Ganor: Well, as I said, we don't discuss future plans. The product right now does not offer voicemail.

Andrew Kantor: It does not, but they may or may not in the future. Any other questions?

M: [inaudible]

Andrew Kantor: Do you use TCP or UDP and what are the implications in terms of firewalls if you only use UDP?

Elon Ganor: We use UDP, and the implications are that firewall's operators. The system operator needs to set it up. We give the technical support in order to set it up in a way that will allow CU-SeeMe to work with it.

Andrew Kantor: Glen, do you use TCP, UDP?

Glen Hutton: Yeah, we use TCP to make the initial connection, and then at that point, UDP. And there are obvious reasons why UDP was chosen by anybody doing this kind of technology — because of potential delays in trying to reorganize the packets.

Andrew Kantor: Are we connected yet?

Glen Hutton: No, I'm working on that.

M: Could you just confirm? Did you say you use 1,100 bits per second, and that's the bandwidth required?

Andrew Kantor: 1,100 bits per second, is that about what you're using?

Glen Hutton: Yes.

Andrew Kantor: I find that fantastic.

Glen Hutton: What was the question again? I'm sorry.

M: 1,100 bits per second.

Andrew Kantor: 1,100 bits per second.

Glen Hutton: I.IK is what I said, no? Did I say that?

M: [inaudible]

Glen Hutton: It's about, I apologize, I'm sorry. It's around I.IK.

Andrew Kantor: It's around I.IK, the bandwidth that you're using.

Glen Hutton: My mistake.

Andrew Kantor: It's around I.IK, the bandwidth they're using, which is why a 9,600 modem won't do the trick.

Glen Hutton: Yeah, that's right. I have a cold, and I'm on drugs, and numbers are a little funky to me right now.

Jeremy Carl: Question over here, yes sir.

M: Two questions, one having to do with standards, and the other having to do with voicemail. Where is the voicemail stored? Is it stored on the server? And regarding standards...is there a standards committee or standards group working [inaudible]?

Andrew Kantor: Okay. So Glen, where is the voicemail stored?

Glen Hutton: The voicemail information ends up being stored on your local POP mail server. So wherever your mail resides, that's where the audio resides.

Andrew Kantor: Okay. Audio resides on the POP mail. Is there any kind of standards committee being set up to maybe link these products eventually?

Elon Ganor: Well, there are some talks about that within the Internet community, but nothing that is specific addressing this between the two different companies.

Andrew Kantor: Okay. So there is some talk, but it's not there.

[Panel]: I would just suggest that for those of you who are really worried about standards, come in another nine to twelve months when the marketplace has been set. I think you could just make a logical conclusion that there is a need for everyone to be able to talk to each other, and whoever the leaders are at that point, you probably will see a convergence of everyone working together to talk to each other.

Jeremy Carl: Okay. We are going to have to wind up. There's a question in back. There was a hand that was up for awhile, I want to take that one question, and then we're going to wind up. Unfortunately, there doesn't seem to be anyone on-line right now. No one to talk to. Yes, sir?

M: Is *Web Phone* going to come out with a Mac version?

Glen Hutton: Yeah, it's in the works. We're actually going to come out with a full-blown 32-bit application hot on the tails of the release of this product, and then we'll be coming out with a Mac version afterwards.

M : [inaudible]

Glen Hutton: I don't have a specific date for you. It definitely is a planned product to be released. The date I can't really say.

Jeremy Carl: Okay. Thank everybody for coming. We're glad we finally got to see the products up there.

HOT NEW TECHNOLOGIES THE WIRELESS FUTURE

MODERATOR

Jane Dysart

Partner, Dysart & Jones Associates

SPEAKER

Larry Bestor

President, American Technologies, Inc.

Jane Dysart: Larry Bestor is presently Chairman of American Technologies, and there you saw a brief preview of some of the products we've developed, and hopefully some of the products that we are going to be developing in the future.

The first thing I'd like to do, before I forget, is thank you all for coming. I know it's late in the day and a lot of us have had a long day. So I'm going to hopefully give you something that's going to be of interest to you and make it worth your while for being here this late in the afternoon.

Larry Bestor: A brief overview of what I'm going to be telling this afternoon is hardware devices, software applications, various wireless communications networks as well as the feature capabilities and uses.

There was a bit in that video you just saw about the current applications. We're going to be talking about future applications, which are really exciting to me because I believe the future in technology, in both Internet access and communications, is in wireless. When you see the prices — and we are going to talk about that a little bit later — you'll find it as exciting as we do.

First of all, wireless access to the Internet. How do you do it? Who has it? What are the uses of this technology now? What's in store for the future? We are going to talk about GPS, we're going to talk about GEOs, we're going to talk LEOs, all the wide-area networks.

First of all, a little bit of background on the global positioning system satellites that were launched by the Department of Defense. [They were to be used] primarily for military purposes, but have now gone into wide scale commercial usage. They were done as a defense measure for guiding satellites, and for use in navigation for aircraft, for military aircraft in times of war.

As it turned out, those twenty-four satellites that were put into orbit over the last ten years have grown tremendously in the use of surveying and commercial use, for navigation purposes and for guiding cars, as you saw earlier. In Japan there are approximately 500,000 navigation systems in cars that will be sold this year. In the United States there is maybe 3,000. So there is a tremendous growth market that we'll be seeing here in the United States if Japan is any indication of what we're going to see.

Next is the GEO satellite, the geo-stationary satellites which we use for communications purposes. Some of you may have heard of or be familiar with the INMARSAT satellites by Intel Sat. These are in 25,000 mile orbits, and are geo-stationary satellites that are used by AT&T, MCI, and others for long distance overseas communication. For data communication here in the United States, we use COMSAT, COMSTAR3, COMSTAR2 and SPACENET3.

Coming in the near future — and being led by Orbcom, a subsidiary of Orbital Sciences Corporation and a company that we develop software for — is the low orbital satellite Radium. You may have heard of it, it's Motorola's project. CTA Space Systems, astronaut Rusty Swigert's company, is jumping into this marketplace. They had a little bit of a bug with a key

launch vehicle earlier this summer, which resulted in blowing up the satellite! But they hope and plan to launch another satellite next year.

Thus far there are two low-earth orbital satellites; Orbcom is in orbit already. Half the work's been done by us, and half by a dozen other companies. The low-earth orbital satellites will be a vast mesh of 30 constellations, of 36 communications satellites in orbit 500 miles above the surface of the earth.

What's exciting about those satellites is that with hardware that is very inexpensive — that is, under \$800 — you'll be able to transmit and receive wireless data communications in a little piece of small hardware with a low power requirement, because of the lower orbit compared to the geo-stationary satellites we have to use today for communications. That's tremendously exciting technology, and we'll see it in '96 or '97. Orbcom plans 26 more satellites over the next two years, and the other companies that I mentioned will be launching their networks, and their constellations will be up.

So by 1997 or 1998 you'll see widespread use of low-earth orbiting satellites for data communication as well as voice communications, and [you'll see] wide-area networks widely in use, as you are probably already aware of. Many of you use a wide-area network if you're in a corporation, a larger corporation that has an enterprise-wide, multi-campus networking problem that they had to solve. Instead of wiring with an infrastructure of hard wiring, they would use a series of radio modems to set up your network.

The biggest [company] — we'll talk about it later — that seems to really be taking the bull by the horns with this is Metrocom, and they're actually rolling out, from city to city, a network or multiple networks of radio modems.

We'll talk first about the satellite access systems, and this system diagram right here basically shows you how a typical tracking and communication system works. Signals are received from a GPS satellite to a mobile unit, maybe a truck or tractor [trailer], and that mobile unit then transmits that position through a satellite transceiver to a geo-stationary satellite; that in turn gets forwarded to the air station, and then through the Internet [where it] can be received by the dispatch side. Anybody that wants to track those vehicles gets that information via the Internet right now, and that's recently a development of the project that we undertook over the last year as a response tool.

A lot of requests from our customers say they want to have a less expensive way to get to satellites, instead of having to dial long distance to the land/earth station. On the coast and internationally there are only a few INMARSAT stations, and they wanted to be able to boost to those land/earth stations less expensively. The Internet became that pipeline, and as a result has been very well-received. The exciting part about that is that it's two-way communication, so those mobile units with a terminal keyboard there in the truck, or inside police cars, can send and receive messages anywhere over North America using COMSAT satellites, and internationally using the INMARSAT satellite. There is a picture of the COMSAT earth station in Maryland, and the dispatch center way out there.

As you can see in the background, there are multiple workstations all tied into the primary dispatch. That happens to be one of our favorite designs, because the central communications fellow sits in the center of a round architectural design in which multiple dispatchers can feed information back and forth to him and communicate.

Current system users include police departments across the country, and we're working with IBM to distribute it in central America — apparently theft is a big problem down there, theft of police cars by police, I think. Truck fleets are the biggest users of the commercial technology here in the United States.

In the United States, commercial fleets make up the major portion of the business; it's about a \$400,000,000 a year business right now by commercial carriers — class A trucks,

primarily. The airlines are using it, and they've been using satellite communications and GPS navigation since it became available. [With] the U.S. military, we have installation at Port Seal and a couple of others where the military has been using it primarily to coordinate command-and-control systems and field operations.

Some of the communications hardware that's available that we've all used, and will eventually be able to go through satellite: cellular phones, pagers — Skytel and M-Tel we're working with, and they've developed an e-mail messaging software that dovetails with our tracking and communication software so they can send e-mail messages through a pager unit, so if you have an inexpensive pager you can use their software to send and receive messages via the Internet — satellite radio transceivers of course, PDAs and notebook computers — notebook computers who are already using PDAs will be used. We don't have any currently in the field, but I see PDAs as a big platform in the future as well.

Here is three-quarters of a picture of a satellite transceiver. For some reason it didn't paint the rest. But with the transceiver itself, you can see the size of it; it's quite substantial. This is a satellite transceiver that [we] would see today, for reaching the COMSAT satellites.

And if we have — reboot, where is reboot? Okay Windows, let's go. Hey, we're all familiar with that, aren't we? This is one of my favorite guys, and that's a Pentium. Well, while we're waiting for Windows to catch up, we'll talk about the Metrocom network as well — there we go — and the availability of that network as it continues to roll out in certain communities.

There is certainly a growing interest in wide-area network technology as well as satellite technology, because of the ability to latch on and be able to send and receive multiple communications, as well as voice communications and data communications, high-speed data communications.

The exciting thing to me about that particular technology is that you will be able to get throughput up to 28.8. Currently we have a limitation of speed through the existing satellites; on the inbound we've got a limit of 14.4, and on the outbound we've got a limit of 48,000 — so speed's a bit higher in that particular network, although it does have localized access only.

[There's a] fight to see if the speeds that we have in satellite are in wide-area networks and ISDN lines, for instance satellites. Well, it's not even going to let me [get] that far this time.

M: [inaudible]

Larry Bestor: This time I'm going to reboot, it looks like.

Let's talk about the future uses we see coming, future uses of satellite technology. We have current communications needs in the transportation industry and in the police department's emergency vehicles, and those will continue to grow and develop. Right now in the transportation industry for instance, communications are required of those transportation carriers that work for the manufacturing facilities, the manufacturing operations in the automobile industry. They actually require that the carriers have to have satellite tracking and have to have mobile communications of some kind.

Cellular is one option, but a very expensive option. It typically runs \$65 to \$300 per month, per vehicle. Right now we can provide satellite tracking and messaging for \$50 per month unlimited, for messaging and communications. [That's a] tremendous cost savings; a recent customer said he paid for this system in the first seven months.

So there is tremendous cost advantage right now and inexpensive data communications via satellite.

M: [inaudible]

Larry Bestor: Hardware? Right, sellers will give it away, almost. Their hardware for tracking, however, is about \$2,000 from a company that's big in that business, [inaudible]. The cost for satellite tracking equipment right now is \$3,000 to \$5,000 if you're in the United States; internationally, using INMARSAT it's about \$5,000 per vehicle. So it's still a high-end piece of hardware, and that's why it's so exciting to see low-earth orbiting satellites coming on-line; once those satellites are available, with hardware that starts at \$800 — and that's pricing from major manufacturers that have been licensed to make the radios. Panasonic is one, SCI out of Huntsville is one, and an Israeli company that will be manufacturing radio.

So there are more manufacturers of hardware that will be licensed to use the technology to manufacture the radios at \$800 — it seems feasible that within the near future, within a year or two after that, we'll have \$500 radios available.

M: [inaudible]

Larry Bestor: Well, currently that's set up specifically by carrier, so that it's like a door-to-door service as your own mailbox on an e-mail service. It works exactly the same way. The only person that can track you — they'd have to have the software, they'd have to have the mailbox name and ID and password in order to get in and track your positions. And that's the same for all fleets, so everybody can track their fleet but not somebody else's. And vice versa for communications.

There is growing demand and a growing need, I think, for inexpensive satellite communication, inexpensive wireless communications. Metrocom is trying to meet that need in localized areas in Silicon Valley, and many campuses — University of Illinois, Stanford University, half a dozen other college campuses — by December of this year they're talking about having mesh topology in place for their technology. By the end of 1996 they are talking about four more cities: Houston, Los Angeles, Washington D.C., and I forget the fourth one. So that mesh will continue to grow.

That topology is set up so a network of wide-area radio modems, spaced about a half mile apart, cross over their radio capabilities so that theoretically when you're in that city you have a radio modem. You lease it from them for \$300, and for a \$30 a month fee you can access your office or the Internet or anything else via radio modem.

So if you're out there mobile, or you're out there in your boat or in your car or whatever, you can get that wireless modem mesh and get to anywhere you could with the hardware or connection. That's available in local areas already, and will be available in more and more localized areas.

But I think that when you consider the implications of a satellite-based system — you have total coverage, endless coast-to-coast coverage. For a little more dollar output per month, you can have coast-to-coast and virtually continent-to-continent coverage. Right now with the COMSAT satellites I showed you earlier, with the geo-stationary satellites, you have coverage from about 88 degrees north latitude down to Central America; so for all of North America you have current coverage today, via satellite, for \$50 a month. It's pretty cost-effective for most communications needs.

Metrocom has an exciting technology there. Another company out already is doing some really exciting things too, with a little thing like you've seen in the Star Trek movies. It looks very similar to it, in fact. When you are within a localized region of it — it has a range of about 400 feet — it can detect to within 10 feet a person's position, and it has two-way messaging capabilities. So imagine a pager that works on an infrared badge; it's very similar to a pager in size, but can track as well as send two-way messages, voice and data. There are a

number of utility companies that are using it, and the government is using it in a number of sites.

There is also about half a dozen college campuses worldwide that are using it. In Europe particularly, they seem to be leading that badge technology, and since Olivetti is based out of Italy, that makes sense.

So for the technology in the future, we see it growing to uses that would include ranchers, bicyclists, adventurers, people that are ballooning, people that are serving remote wilderness areas, any place that you need to be able to communicate [where you would do it] currently with a cellular phone but may not have a cellular network. It will be accessible by satellite and in many cases is accessible by satellite today.

That will continue to grow, and I think we'll see more uses as people take smaller and smaller computers out into the field, PDAs and eventually wrist radios and hand-helds. We'll see more and more communications, to the point where we will see data communications and voice communications for maybe the wristwatch that Dick Tracy was all about years and years ago. We'll see it happen literally in the next three years; in the next three years the capability with LEO satellites and smaller and smaller technology will be available.

So it's exciting. Wireless technology is an exciting, fast-moving field with the advances that are going on satellite launches over the next 24 months, and especially with the additional licensing of hardware to utilize those communications networks and those satellites. We're going to benefit as consumers to a tremendous degree, both from inexpensive communications, data and voice communications, as well as being able to benefit from the uses of that technology at a lower price than you can make a long distance phone call today.

M: [inaudible]

Larry Bestor: No, none.

M: Is it reliable?

Larry Bestor: It has been. We literally had communications through thunderstorms and lightning storms. We tested in all parts at all different altitudes, and we really don't have any problems with weather.

M: [inaudible]

Larry Bestor: None that we really experienced. Now, I imagine that sunspots and electromagnetic activity could have an influence and an effect on low-orbiting satellites, but until enough get up there — at least 36 satellites — to really produce some effective test results we're not going to know for sure. But at this point in time the GEOs have been performing really well for a long time, and it's a technology that's just being applied to a lower altitude and a wider network of satellites. Hopefully we'll have the same results. Yes.

M: [inaudible]

Larry Bestor: Exactly. A person that comes up with high throughput through a satellite that's inexpensive to build — by Hughes or Rockwell or one of the major satellite manufacturers — will be a very wealthy person, because that is a very valuable technology that does not yet exist. Yes.

M: [inaudible]

Larry Bestor: Throughput right now, inbound, is 14.4 and outbound is 48 baud. For bandwidth — to put that in numbers, in real numbers, the satellites right now handle about 200,000 subscribers, and that would be an average of — well, consumption on that is about 2 million bits of data per hour, so the volume isn't there to handle the kind throughput on the Internet that we would like to see at this time.

Now, in the future it can be [there], but currently it doesn't exist other than for voice and communications and text-type transmissions. In other words, we're [going] to see huge video conferencing going through satellite transmissions, but it's just not real feasible for that capability yet. Yes.

M: [inaudible]

Larry Bestor: There is a similar technology to what you are describing by Rockwell systems. The Rockwell radio that's currently available will switch from a local network, and if that's not available to the radio it will jump to INMARSAT. So it's intelligent enough to do that. That's the only one that exists. But there is no one that I know of that combines cellular and satellite. Cellular is a very expensive option.

M: [inaudible]

Larry Bestor: Yes, and primarily that will be a real advantage for voice and high-volume data transmissions in the future. That's yet to be played out, and I don't think the jury is in yet to decide how well that's going to perform.

There are a couple of companies that have vested stakes in seeing that perform, and there is some tremendous potential available. [With] CD video technology we haven't seen it applied, but certainly in a large volume of video transmissions.

M: [inaudible]

Larry Bestor: Who are the players? Qualcomm and [Loral]. And everybody is familiar with Qualcomm; Qualcomm is CDPD technology. I thought I saw a hand over here.

M: [inaudible]

Larry Bestor: I haven't seen that, so that's a good question, I will have to check that out.

M: And at a tremendous megabyte per second, 2 megabyte per second rate, I think. So it's very, very fast.

Larry Bestor: It relies on the hardware, as I understand it.

M: Well it's not mobile, it requires a repositioning with each physical movement of the receiving [inaudible]. But it could easily be used on a camper or on an RV that moves about and then sits there for a while, long enough to make the repositioning worthwhile.

Larry Bestor: It's very similar to the early satellite TV dishes that we saw on RVs that would pop-up in position for a satellite lock-on, and when they were done they moved it and lowered

the satellite dish. That's quite a bit different. The antenna we're using right now is about this big around, with a whip antenna about that long. It doesn't have to be positioned; it's a non-directional antenna, which is ultimately the best. We'd like to see. The Hughes design sounds like a good one, they just have to get the antenna and the reception down.

All right, thank you for coming. I have nothing else, and since the computer is not going to come back up again you just missed some great pictures.

There is one more thing I'd like to do. We have a... You have it? Okay, I'm just going to run through those real quick.

I'd like to introduce Bill Robinson. I don't know how many are familiar with Telos Corporation. Bill represents Telos Corporation, a licensee of our technology that provides satellite tracking services to the U.S. government on a large scale. Internationally they have been doing it for years. And he will be here to help answer questions you might have after we're finished.

M: [inaudible]

Larry Bestor: And Toshiba still makes a good notebook computer.

M: [inaudible]

Larry Bestor: \$299 [from] Metrocom. They are more expensive in other places. That's the lowest price I've seen.

M: [inaudible]

Larry Bestor: They vary in speed from 9,600 to 28.8. They have more expensive versions for \$599; they have from \$299 to \$599.

Okay, we talked about Metrocom. Why don't you back up a minute there Bill — you know how to [go] backward? I think it's this button here.

M: [inaudible]

Larry Bestor: This isn't connected here... Oh, it is, okay.

[Logitrack] software is the software that we developed for doing that on-line using the GPS satellites, communications satellites and the Internet. So you have the ability to really combine those three technologies, the communications and navigation technologies as well as mapping technology to provide a graphic representation in the Windows environment of the position of the vehicles you're tracking. And that will track you with the accuracy of the GPS received, so if you have a typical C-code GPS unit, that's accurate to about 100 feet.

If you have a differentially corrected GPS unit, that would be accurate to a meter. Metrocom's ricochet wireless radio networks already provide high speed access to the Net.

Here are the service areas that currently exist, and Seattle is late '95. Boston was one of the cities scheduled for late '96, Washington D.C. in early '96, and the areas up above are areas that are already covered by the ricochet service. As you can see they are very localized coverage areas because of the tremendous infrastructure they have to build in those localized areas in order to cover it.

The wireless networks that exist, [the ones that have] currently rolled out the alpha development product list are on this list here: Xerox PARC and DEC — who seem to have some really aggressive technical people that love to have the neatest toys — MIT, Media Lab,

Cambridge and Velcor. All the rest up above are in Europe. That's the Olivetti badge, as I talked about earlier.

What's kind of exciting about that particular technology is that it will transmit that unique infrared signal every ten seconds, so that literally you can identify, from a tracking center like we showed earlier with our [Logitrack] software, exactly where in a building everybody is by their particular ID. It just reads the database and puts in the name or the number of the individual you want to track.

What does the future hold? Shipping fleets, tracking containers — and putting sensors on refrigerated units is a tremendous market in the future. We've had calls from people in the Caribbean, and there is a company that we partnered with call [Caribsat]. All they're going to do is market the technology to cargo container companies, because [those companies] want to be able to monitor, when they're shipping a cargo of bananas from South America to the United States, what the temperature in their refrigerated cargo container unit is.

If the temperature drops by a certain amount an alarm goes off and sends a signal out to the satellite, and that in turn alarms somebody that some preventative correction and maintenance can be done. Otherwise, generally they'll go down in those cargo holds in those ships, and nobody ever checks those cargo containers until they arrive at the port. By then a whole shipment could be lost — hundreds of thousands of dollars of produce. So that's a very important market in the future.

[There are applications for] telecommuting, which we all do, and we'll do more of it in the future. Balloonists I talked about earlier, cyclists — there is a fellow traveling around the country right now, a journalist, fascinating individual, and he has every techno-gadget you can imagine on his bicycle. He just bicycles everywhere, through rain or shine — it's totally enclosed. He has a notebook computer with a navigation system built-in the notebook computer, and could tell where he is and communicate wirelessly with the companies and the wire services.

Ranchers, of course. That's a big one.

Any remote sites — wilderness mappers, surveyors, road warriors.

Urgent search-and-rescue operations can be sped up so lives can be saved.

[There are applications for] remote adventurers and imaging — I can imagine e-mail messages being sent from the next Mount Everest expedition.

For cruisers, people out on a ship, if they want to contact the office or send e-mail back and forth, you can spend more leisure time and still get your work done.

Okay, and watch children. This is a big one — a combination of technology which is a little bit broader use of the Olivetti tabs that are able to identify individuals and certainly will be able to track their whereabouts. We will be able to put them in the clothing of children and be able, from our home computers, to identify where they are at any time.

Another important one: the Dick Tracy wrist radio. I'd say three years, tops, and we'll see those. And, of course, accessible remote databases when you're out on your runs.

My last one is my favorite: transporters. Eventually I think we will be able to see, with the continuation of wireless technology, DNA restructuring and mapping and the transporters that we all saw on Star Trek.

And here is more info on the Web. I'll leave that up there for a while so you can copy those down. Thank you for your attention, that's all.

TUTORIAL INTERNET 101

SPEAKERS

Andrew Kantor

Senior Editor, *Internet World Magazine*

Eric Berlin

Contributing Editor, *Internet World Magazine*

Andrew Kantor: [Let's start by giving you] a general idea about what the Internet is. Well, you have obviously read *Newsweek* and gotten some idea of it, or you have seen *60 Minutes*, so you have an idea that there is this Internet thing out there that is obviously important. But what is it?

Is anyone here not familiar with computers at all? No? Good, that saves us a whole lot of trouble if you know how to use your computer.

So, there is this Internet thing — you want to know what it's all about. You keep hearing about all this wonderful information out there on the Internet. You keep hearing about how everyone is getting connected to the Internet — my company is on the Internet, this company is on the Internet — what does all that mean?

Eric Berlin: What does it mean to be on the Internet? Where is it?

Andrew Kantor: Yeah. You hear terms like “Information Superhighway” and “global computer network,” and it does not mean anything. What does that mean, information superhighway, global computer network? What is that all about?

We are going to try to give you an idea. We are going to give you an idea of exactly what the Internet is so you can walk out on the show floor, and then when you see a company and they say, “We do Web servers,” you'll say, “Oh, I know what that is.” Or if they say, “We provide e-mail software,” you can say, “Oh, I get it.” You will be able to understand what this is all about, and we'll give you a foundation for everything else you need to know for the rest of the show.

We are also — obviously, as you can read — we are going to cover what people do on the Internet and why it is such a big deal.

M: Do you give out handouts?

Andrew Kantor: Do we give out handouts?

Eric Berlin: We gave out handouts. Everybody has one by now, right?

Andrew Kantor: Oh, good. Onward we go. In Part One, as it says, we are going to cover exactly what the Internet is and what is on it. We are going to try to give you a good analogy for what the Internet is.

Imagine that somewhere there is a shoe company. They make shoes, like Florsheim and Dexter and a bunch of others. And they have information on their computers; like most companies nowadays who have computers, they have got a lot of information on their computer. They have their inventory, they have designs for shoes, they have personnel records, all that kind of stuff. That's great, and they use their computer a lot and they keep a lot of information on it.

Let's go back. The shoe company does a lot of business with a leather company for leather shoes. The leather company also has a computer and the leather company also puts lots of information on their computers. They put personnel records, and what cows are being killed this week and what is coming in and what the various companies they deal with are going to need in the next couple of months. They have that kind of information on their computer.

Of course, the people at the shoe company are always in contact with the people at the leather company because they need information. What kind of leathers do you have? Are we going to run short on inventory? Or rather, we are going to need a lot of this and make sure you have that; do you have anything new coming in that maybe we want to make shoes out of? They are always in touch and they are always on the phone with each other.

So one day they come up with a bright idea: why don't we hook our two computers together? The idea is that this way, rather than call you up — we are a 24-hour-a-day shoe manufacturing company — rather than call you up and say, do you have this leather in stock, or what about this or what are you getting in, we can just tap in to your computer from our computer. Computers can do that.

Now, of course, we don't want you to have your secret information, personnel records and stuff available to us. We want just the stuff we need, if you can make that available to us. And we'll put information on our computer and make it available to you at the leather company, so that if you need something from us, if you need to know what quotas we are trying to fill, you will have the leather ready.

In other words, we both have computers, we both use information, we use a lot of the same information, so let's connect our computers together. So they decide [to do it] and they call Sprint or AT&T or MCI or any major communication company and they literally have their two computers wired together across town.

Eric Berlin: Let me draw a picture of that.

Andrew Kantor: Voilà - and it was good. It works really, really well. Great, we can share information, and people at my company can get information from your company. People from your company can get information [from my company]. It's a great idea.

The shoe company says, "this is working so well, now that we can exchange information, that we should do the same thing with a rubber company, the same deal. They have some information that we need, and vice versa." So they again call Sprint, AT&T, Wiltel or whatever, and wire themselves to a rubber company.

Now the shoe company can share information with either one. Everyone following this so far? Good. So now we have the shoe company, the leather company and the rubber company, and they're all wired together. Now, a side benefit of this is that anyone at the rubber company can also get information from the leather company; the same information that is available to the shoe people — why the people at the rubber company would want it, I don't know; in fact, they probably wouldn't, but because they are all connected — well, this works really, really well. So at the shoe company and the rubber company and the leather company, everyone says, "this is a terrific idea hooking up our computers. Let's keep going."

They start hooking up a podiatric college — "hey, tell us the latest orthopedic designs. We want to get information." The rubber company hooks their computer to a tire company, and, of course, the [rubber company] makes toys, so they hook up there. So people are getting the idea of hooking their computers together so they can share information — and, again, not all the information, because the rubber company is not making their personnel records available to the tire company, Goodyear or whoever — but they are making some information available on all their computers in this little town where these six companies are connected.

Everyone catches on to this idea and it expands and expands and expands. Colleges, universities, textbook companies, toy companies, auto repair shops, everybody says, “hey, everyone is calling up Sprint or AT&T or MCI and saying, hook me up to this other guy because they have got information I want.” What is really neat about this is that once everybody is connected like this, someone — say the textbook company — is indirectly, but very much so, connected to this automobile company’s computer.

Now every organization that has connected computers in this little group here has put in only certain information, made only certain information [available] to everyone else. So the textbook company looks at this auto company’s computer and they see stuff that has to do with automobiles. They may or may not use it — maybe they have a textbook on repairing automobiles — but these people can all get information. This is a neat idea.

One point is, who is in charge of all this mess? Nobody, obviously. Originally, the first connection was between the leather company and the shoe company. They were the first ones, but Neil Armstrong is not in charge of the moon just because he was the first guy there. So nobody is in charge. The textbook company pays the phone carrier for this line, and everyone else is kind of just paying their own way. Everyone with me so far?

So, picture this little town with a dozen or so organizations’ computers connected, and that’s exactly what the Internet is. What you saw is, for all intents and purposes, exactly what the Internet is, the difference being that instead of a dozen computers in this fictional town or city that we had there, the Internet is seven million computers in over 100 countries around the world. But it works the same way; there is no central computer. There is no computer in Alexandria, Virginia, that is “The Internet” that somebody runs. There is no Internet, Inc. Nobody is in charge of all this, just as nobody is in charge of that little group of computers in the small town.

Eric Berlin: Because it was something that evolved.

Andrew Kantor: Right. Everyone just started kind of connecting, connecting, connecting and it got bigger and bigger and bigger; and someone who connects in Japan is, by default, also connected to a computer in Boston. It all kind of comes together.

So when someone says there’s something on the Internet, what that means is there is something on one of those seven million computers, something on this little city network — maybe the shoe company or the podiatric college has suggestions for babies, and what kind of shoes babies should wear at what age. They put it on their computer so that people at the shoe company can see it. That is on this network.

Anyone who works for an organization that has a computer on the Internet can put information on their computer. If it is on their computer it is on the Internet, and that’s very important. It is kind of like [saying that] if you have a chainsaw in your basement, there is a chainsaw in your neighborhood. Same thing here; if you have something on your computer and it is connected to the Internet, it is on the Internet. It is a very important concept and the reason I am going over it several times is that it is going to come back a lot later when people talk about things that are on the Internet.

So everybody is in charge of this mess. There is nobody running it at all. The cost is distributed like in the example I was giving — the shoe company pays Sprint, whoever, and the shoe and the leather company pay them to wire their computers together.

Everybody who is on the Internet pays for their own individual connection to the Internet. There is no one running the whole thing. You do not call Internet, Inc., and say, “connect me,” like you would call the phone company. If you want to be connected to the

phone system you have to call NYNEX or whoever, maybe Pacific Bell. You have to call them to hook you up to the phone system.

This does not work that way. The phone system is out there — or in this case, the Internet is out there. You can pay anyone who is willing to connect you to this. You pay your own way. You are not paying a central authority — and this is very, very important.

Distributor responsibility, distributed information. When you put something on your computer, that computer is on the Internet. Therefore, you are responsible for stuff that is on the Internet. If you work at that podiatric college and you put the wrong information about what shoes should be worn by what age babies — well, that is your problem. You put that information — you are responsible for what is on your computer.

You are responsible for what is in your house. If you have a bomb in your house and it goes off and it burns down the neighborhood, you are responsible. Anything that you put on your computer that is on the Internet, you are responsible for the accuracy, the timeliness, etc., etc.

It is very important. Information on the Internet is whatever the people who work for the organizations that make it up want to put there, whatever they feel like making available. That shoe company may want to make some interesting information available about shoe leather and what wears better and what leather is waterproofable; maybe they don't. Whatever they want to make available [they can]. That's very important.

Eric Berlin: And the flip side of that is that if you do not want somebody to display a particular piece of information there is really nothing you can do to stop it, because nobody is running the Internet. There is nobody to complain to. This is why pornography on the Internet is such a hot issue, because there is no central authority.

Andrew Kantor: We are going to be getting more into this a lot later.

Eric Berlin: It is also not a particularly big problem anyway.

Andrew Kantor: This is the picture we need you to have of the Internet, and everything else will just click into place like little points of light. It is an experiment in anarchy. Nobody is in charge. Everyone kind of sticks in their own computers and connects it together and, hey, it works.

Eric Berlin: Just very briefly, this anarchy was created by the United States government. You may wonder who that original shoe company was — it was the government trying to come up with a system that would allow computers to talk to each other in the event of a city being blacked out or a nuclear war or something like that.

Andrew Kantor: Because [the government] knows all these companies, the shoe company and all that together. If the shoe company was not there, the other computers still are and the other computers can still talk to one another. So that was the idea the government wanted to create — a bomb-proof computer network. They created it in 1969.

Eric Berlin: Others saw it was such a wonderful new network, a wonderful new technology, that they built other networks using that same technology in other parts of the country. Then they all started evolving, started connecting to each other in a pell-mell fashion until we have the big mess of the network that we have today.

Andrew Kantor: So the government started it, but the government has very little to do with it anymore. It is one of the many organizations that has computers on the Internet, but the government does not run it, they just came up with the idea for it. Question?

M: You say that no one owns the Internet, but only an Internet provider will let you pay them money to give you access to the Internet.

Andrew Kantor: We will wait and talk about providers in just a little bit.

M: Okay. Will you about what you are paying them for, what they are connecting you to?

Andrew Kantor: All this information on the Internet.

Eric Berlin: All this and more.

Andrew Kantor: Whatever people choose to put there. Yes, the Internet is the precursor to the Information Superhighway. If you are a journalist — I don't know if we have any journalists here, I don't see any press tags — but if you refer to the Internet as the Information Superhighway, that tells me you don't know what you are talking about. Anyone who refers to the Internet as the Information Superhighway is clueless in my book. Al Gore just a few years ago said, "Someday all Americans will be connected to an Information Superhighway, with on-demand news and videos and audio and all that, and that will be a wonderful day."

Well, someday that probably will happen and we are seeing the beginnings of it now, but that is the Information Superhighway, otherwise known as the National Information Infrastructure, NII. It does not yet exist. The Internet is the precursor. This is kind of the idea that it will be built upon, but the Internet is not the Information Superhighway, except if you are in marketing or a PR person and say, "We'll get you on the Information Superhighway."

Eric Berlin: All it is is a catchy catch-phrase.

Andrew Kantor: And it's a kind of an overdone catch-phrase. If any of you ever use [an expression] like "I feel like road kill on the Information Superhighway" or "an on-ramp on the Information Superhighway," I will find you and beat you over the head with this microphone. It's just bad.

In the end, the Internet is just a big bunch of computers. It is just a whole bunch of computers around the world, seven million or so computers around the world that are connected. There is an organization — actually there are several — but in the United States there is an organization in Virginia called the Internet Network Information Center that was originally funded by the government, but is no longer [funded]. Their job is to keep track of who is connected to the Internet and make sure that everyone knows about everybody else that is on the Internet.

"Hey, a shoe company just connected, hey, a college just connected." That's their job, because without them it would get very confusing, so it's good. Right now it's run by, I believe, AT&T and a company called [Merritt]. But it's a good thing.

That's all the Internet is — just a big bunch of computers. And, of course, what's on it? Lots and lots and lots of information. If you can imagine that little network I showed you before, what kind of stuff the shoe company, the leather company, the toy company, etc., puts on — well, now you have got seven million computers, several thousand organizations. They put lots and lots and lots of information, all sorts of different things. NASA is connected; NASA

puts pictures of space shuttle launchers and pictures of planetary probes and whatever they feel like, whatever the people running NASA or JPL or whoever want to put up on their computers that it connects to the Internet.

Some guy may say, "hey, I'm connected to the Internet. I got a computer. My company has a company. I'm going to put a picture of my dog on there because I want to." He puts it on his computer, it is therefore on the Internet. Other people on the Internet, if they can find it, can see it.

Governments put information on the Internet. The U.S. government has plenty of it. If you want to find out the state of a bill in Congress, you can find it because the government puts it on their computer. Their computers are connected to the Internet. It's like a mantra: it's on their computers, their computer is connected to the Internet. That is what information on the Internet is all about.

Which means — and this is, again, back to this important thing — what is on the Internet? What is on these computers? It might be right or wrong. It might be funny, it might be offensive, it might be outdated. It might duplicated. It might not be there at all. It's whatever these people want to put on there.

The Aryan Nation has a computer connected to the Internet, and they will put information on that you may not like. The Christian Coalition, Mothers Against Drunk Driving, any of these organizations can put stuff on that you may or may not like. You may not like this religion, you may not like this philosophy, you may not like these people, you may not like this country, but these people are all putting information on the Internet.

Eric Berlin: We are going to be making a lot of comparisons between the Internet and an on-line service because they are two entirely different things. One of the things that separates them is that an on-line service is in charge of what is on its computer.

Andrew Kantor: An on-line service being CompuServe, America Online, Prodigy.

Eric Berlin: If you want to upload a file to a forum on America Online or Prodigy, there is going to be somebody there to take a look at it first before they make it publicly available.

Andrew Kantor: Somebody is in charge. Somebody owns CompuServe. Somebody owns America Online. Nobody owns the Internet. Imagine if your home computer was connected to the Internet and you could make what is on your computer available to anybody. Well, it's your computer; what do you want to put on it? You could put bad poetry on there. You can put pictures of your dog. You're mad at your ex-wife? Put naked pictures of her on there. Whatever you want, it's your computer — but other people can get it.

Let's say a company has a bunch of computers, [and has] like 50 employees and they all have computers. That company is on the Internet. In general, one computer is on the Internet and then the employees can connect to that one computer very easily. So in some cases, employees can actually — their computers can be on the Internet. It depends on whether the company wants to set it up that way.

At my company, the magazine *Internet World*, we have one central computer. My computer is connected to that central computer, so I can put stuff onto the Internet from my desktop machine if I want to. That is the way my company is set up. Most companies won't do that because they want to have some control over what their employees make available, so they have one computer that represents them.

That is what I mean. There's no control. It is kind of a misnomer to say there's no control over what is on the Internet; what's important is that people are responsible for what

they put up. If you put libelous information on your computer, that is not to say you can do it and then there is no legal recourse about that. That is illegal, and you can be sued for libel because it is on your computer and because you have said this and you have put it up. So no one can tell you what to put up and what not to put up, but the laws still apply.

Child pornography is a big one. If you have child pornography on your computer — it's illegal to own child pornography in the United States. Therefore, you can put it on your computer and no one can prevent you from doing that, because there is no censor checking it, but if you do that you are going to be in trouble just as if you put it in the windows of your house. So if you put libelous information or information that is clearly wrong or illegal on your computer and someone else sees it, you are responsible for it. You are legally responsible for what is on your computer, although there are some interesting questions about [the possibility that] someone else put something on your computer.

Eric Berlin: We are going to be getting back to connectivity in a big way.

Andrew Kantor: When we talk about computers on the Internet, generally they are called "servers" or "hosts." These are fairly large, often UNIX, computers, mainframe computers. They're usually larger, more powerful computers that companies use to connect to the Internet.

Eric Berlin: Then individuals connect to those servers either by dialing in with a telephone and a modem or by connecting via big, fancy wires.

Andrew Kantor: If your computer is on the Internet and you want people to get information from it, you don't want to ever turn it off. You want a big computer that is always on that people in your company and outside your company can get access to.

Eric Berlin: We will go into much more detail than that in a little bit.

M: [inaudible]

Eric Berlin: The U.S. government regulates how phone book companies can distribute their information. NYNEX, the New York Phone Company, is getting around this. They are getting around this by posting their yellow pages on the Web on a server in France.

Andrew Kantor: On the Internet. We will talk about the Web later.

Eric Berlin: Right. On the Internet in a server in France.

Andrew Kantor: U.S. regulation basically says that if you are a telephone company you cannot put information on-line. Or they did say, very recently, that you cannot put information on the Internet. That is U.S. regulations. And NYNEX said, "okay, we will put it on a computer in France."

Eric Berlin: There is no nationwide lottery because the United States government will not allow a nationwide lottery. That might change, But in the meantime that is the fact. This does not effect the country of Liechtenstein.

Andrew Kantor: Liechtenstein has got a government lottery that you, as an American, can buy a ticket to.

Eric Berlin: A worldwide lottery. You can just go and give a credit card number and enter a worldwide lottery.

Andrew Kantor: Gambling is very big.

Eric Berlin: The answer to your question is that there is nothing to stop anybody at this point.

Andrew Kantor: It is the lowest common denominator. The example I give, just because I've been talking about pornography on the Internet, [which is] this horrible problem that doesn't really exist. In the United States you can't have naked pictures of yourself if you are under 18. In most of Europe, it is under 16. So it's kind of like the lowest common denominator; you can get pictures of people in Europe because that is their law.

Gambling companies — it is illegal to do on-line gambling, and there are all sorts of U.S. regulations involving gambling. So these gambling companies said, "Okay, we'll put it on a computer in Belize."

When you are on the Internet you learn how amazingly restrictive the U.S. Government is and how we are living something so far from a free country as — the rest of the world kind of laughs at us. People using the Internet get around regulations of various countries all the time and put information on that they are not allowed to have in the United States. They will put it on a computer somewhere else so the people in the United States can get it.

It is even more interesting when someone in California violates a Tennessee or Alabama law and someone from Tennessee or Alabama sues the company in California because, well, my computer can get to your computer. You have something that violates Tennessee law on your computer, therefore I am going to arrest you for violating Tennessee law in California.

Eric Berlin: There was an adult bulletin board in California which a community in Tennessee felt violated their community standards law, and so they sued on Tennessee grounds.

Andrew Kantor: They arrested him and they won, although it is being appealed. They won the first suit and then I think they lost on appeal.

Eric Berlin: It is really quite a hoot when you think about it.

Andrew Kantor: The laws of the world are going to come down to the lowest common denominator because you can always find some country that will let you put some information up somewhere.

It becomes very interesting. In the United States, if you libel somebody, if someone sues you for libel, they have to prove — you can say, "oh, but the information is true and in the United States truth is a defense for libel." Not so in England, where truth is not a defense. They can say, "no, you still said something bad about somebody." Okay, so you're in England; you want to say something bad about someone? Say it in the United States.

All right, [back to the Internet]. What is on all the computers? All this stuff is on these computers. *Alice in Wonderland*.

Eric Berlin: And then some.

Andrew Kantor: And then some. *Alice in Wonderland* is there because the copyright has expired and someone has taken the time to actually type in or scan in or somehow get into their computers the full text of *Alice in Wonderland*. It is called "Project Gutenberg." They are trying to get every book in the world electronically on the Internet, and they are doing a very good job.

The *CIA World Fact Book*, [which has] all sorts of information about countries around the world. The CIA says, "okay, we can declassify this. We will put that on our computers on the Internet." The Bible [is there] in many, many forms, because they can't find the copyright holder. *Playboy* magazine is there because *Playboy* wants to put in the text. Do you want to find *Playboy* interviews? The best place to find it is on the Internet, because all the interviews are back there and it's a lot easier than going through the library or looking under your mattress.

AT&T has put their 800 directory there. Why? Because someday everybody is going to be on the Internet. Why? So these poor little 800 operators have to answer these phones. Why don't we just make our computers available to the rest of the world through this Internet thing? If I want to look up an 800 number now, and I am on my computer, it is easier to go there than to actually deal with an operator.

Eric Berlin: Along those same lines, FedEx allows you to search by tracking number to see where your package is. You do not need the tracking software that they were advertising a month ago; all you need now is to go onto their site on the Internet.

Andrew Kantor: UPS, Airborne, they are all doing the same thing. They have information on their computers that is for the public. If some of the public can get there directly and not have to deal with the middleman then that is one less person we have to pay.

Pizza Hut lets you buy pizzas through the Internet.

Eric Berlin: As long as you are in San Jose.

Andrew Kantor: Just type in your zip code and they can deliver to you. You can order a pizza through the Internet.

My bio is up there. I have information on the Internet because my company is on the Internet, and I paid someone to put my information up. We will talk about that in a little bit, but I put information about me up on the Internet because I wanted to.

How do you get on the Internet? You need a few things to get on the Internet. The first one is rather obvious, and if you did not know this already you are in the wrong seminar: you need a computer. It can be a PC, it can be a Macintosh. Faster is better. We will go into a little more detail in a moment about what you need.

So you need a computer and you need a modem, the faster the better. A modem is a device, for those of you who do not know, that connects your computer to other computers through a telephone line.

Eric Berlin: This should indicate to you that we are not talking in the seminar about corporate connectivity, how to set up your company on the Internet, etc. — we are simply talking about you, the individual, with your computer and your modem.

Andrew Kantor: Although companies and corporate connectivity is very similar, just on a larger, more expensive scale. Kind of like if you take a cab by yourself, it costs like \$5; if the company pays for it it's \$25. It is the same thing.

You need software to get onto the Internet. It used to be that you didn't, that you could use just about anything out there, any kind of communication software that came with your modem, the cheap stuff. But nowadays, in order to get the most out of the Internet or to get anything real out of the Internet, you need Internet access software. You can buy it, you can get free samplers in the back of books or you can get it from your Internet access provider.

You need an Internet access provider, those companies on that little map I showed you. If you go, say, to the guy at the shoe company, and say, "you have a lot of great information in this little network you have, about the toy company, the colleges. I would like to hook up my home computer to get information from this little network you have." The shoe company is going to say, "you think I am going to waste my time letting you get connected to this? No way." These companies on the Internet have better things to do than to hook you up.

So what has emerged are companies called "Internet access providers." They get themselves hooked up to the Internet the same way these other companies do — Sprint, AT&T, whatever — and they say, "Our business is selling access to other people. We will let you connect to the Internet through our computers. Our computer is on the Internet; you connect to our computer using your Internet software, modem and computer and then you can get access to all the information that is out there. Furthermore, you can also put information on our computer which is on the Internet, so you can put your own information up there." But Internet access providers, or Internet service providers — IAP, ISP — their job is to hook people and organizations and everyone else to the Internet. They are connected already. It's wholesale and retail. "We are connected. We will sell it to you."

Talking about computers... In the old days I would say — like when we gave this seminar a couple of years ago — that any old computer will do. You can use an old IBM XT with a monochrome monitor and you can get on the Internet. You still can, to some extent, except that with much of the Internet now you need graphical software, and better software to access it, so that's no longer exactly true, unless you are willing to learn UNIX.

For those of you who know DOS, UNIX is like DOS but harder and less intuitive, believe it or not. But nowadays you need good software, you need Internet software to get onto the Internet. If you want to learn UNIX we can talk about what are called "shell accounts," where you are typing in UNIX commands to get stuff off the Internet and you are not seeing any pictures. It is still possible; but for normal people, you need a good computer.

There is also all that multimedia stuff. There are lots of pictures and sounds and animation and who knows what, and for that you need a better computer. So if you are going to buy a computer, you can get a PC or a Macintosh, although you will find that a Windows PC is a much, much better computer for accessing the Internet for one reason only, and that is because of the amount of software that is available.

So you can use a PC or a Macintosh, and the faster the better. The newer the better. You want to be able to run Windows or Windows 95 as Windows 95 applications come out. With a Macintosh, you want to be able to run the latest software. There is software now for a PowerMac; you want to get a PowerMac if you can. Again, the faster the better.

If you have a computer now and you are running Windows or you are running System 7 on the Mac, you should be fine and you should be able to get software, so don't run out and buy a new computer. But if you are going to buy a new computer, get the fastest and the best you can because all the new software is going to require faster computers with more memory.

Eric Berlin: It already does. And the applications that are available on the Net are just remarkable, including animation and multimedia. Virtual reality is what we're moving into soon.

Andrew Kantor: Anyway, about buying a modem — this is very simple. Buy the fastest modem you possibly can. Not the fastest you can afford, the fastest that is available.

Eric Berlin: Use your credit cards. You will regret it otherwise. A 28.8 modem is presently the fastest available.

Andrew Kantor: 28.8 modem means... Does anyone not know about modems and modem speed? Modems are rated in speed. The modems that are around now are in bits per second: 2400 bits per second, 14,400 bits per second, 28,800 bits per second. The higher the number the faster the modem. Very simple.

You want a 28.8 modem because that is the fastest you can get. It's also called a V34 modem. If you have a choice between a faster computer and a fast modem, get a fast modem. Spare the PC, spoil the modem. Get the fastest thing you can possibly get. That's the most important thing about your connection and it is worth every cent, just as getting a slower modem will be worth every cent because they're pretty cheap. You can get a 14.4 modem for \$89 or less. You'll probably spend \$150 to \$250 for a 28.8 modem, and it is worth the extra money.

Software is tough. Why is it tough? Because there's so much out there and so many different ways to get it.

Eric Berlin: What people are packaging and putting out on the market are what are known as "Internet suites." They took a program that will let you read your e-mail, a program that will let you look at UseNet News — and you'll see all this soon — programs that will let you use every facet of the Internet. They put it all into a box, along with a dialer that will let you use your modem to connect to the Internet, and they put it on the shelf. Most of these are for Windows. The best ones are *Internet in a Box*, *Internet Anywhere*, and *Internet Suite*.

Andrew Kantor: The commercial software that is out there for the Internet costs anywhere from \$39 to \$150. There are lots of different packages out there and they all do basically the same thing, which is connect you to the Internet. And they let you do the same things on the Internet, which we are going to go into for the rest of the seminar. That's all they do.

Eric Berlin: Here's the thing: Once you're connected to the Internet it doesn't matter what software you use. If you like the mail reader from package A and the news reader from package B, you can do that. There's free software out on the Internet, there's free software that's better than the commercial stuff, basically.

Once you get a dialer and get yourself connected to the Internet, once you learn how to get this terrific e-mail program from this site on the Internet and get this terrific news reader — we'll be telling you the names of these terrific things later on — from this side of the Internet, [you can] set up your own little personnel Internet software suite.

Andrew Kantor: But basically, when you're starting out you want to buy software. It's very easy to set up nowadays, especially since a lot of them come with preconfigured providers; if you use such and such as an Internet provider it's all configured and it's easy to set up. If you don't, it takes a little longer to fiddle with some numbers.

It's very easy to set up and you can mix and match. Buy one suite, and after a couple of weeks of using it you can switch with something else. There's a lot of freeware and shareware software out on the Internet that you can use and that you can substitute. And it's really good stuff.

For Windows, the best product, in my opinion, is *Internet in a Box*. They're all very good. That's the thing, they're all really, really good, like *Internet Anywhere*, formerly by a company called MKS. *Quarterdeck Internet Suite*, [Walagon] *Emissary*... You'll see a lot of these products out on the show floor if you go there. All this stuff is really, really good stuff.

For the Macintosh there's a program, a very old program, called [Versiterm] *Link* which has not been updated in awhile, and there is *Netshark*, which is fairly new from a company called Intercon. That's it. *Netshark* is the only thing out there that's not entirely complete. I don't think it has a news reader; I think it's missing some very important piece of software, but for a Macintosh it's the only commercial product available.

On the good side for the Macintosh is that there's tons and tons of Macintosh software on-line that you can get out on the Internet that you can get copies of.

Eric Berlin: The problem is, though, you have to get on-line before you can get that software.

Andrew Kantor: If you buy Internet books, a lot of books have access software disks in the back of them. That's probably the easiest way. Once you get connected to the Internet, you can create your own little connection of programs.

Eric Berlin: As Andrew said, most of the commercially available software is preconfigured for national Internet access providers. You need an Internet access provider who is basically — it's a big computer out there, and you're going to pay them money and they're going to allow you to connect to their computer and thus to the entire Internet. The major pieces of software are preconfigured for national providers like NETCOM, PSI, and CompuServe. [With CompuServe], besides their on-line service they are also an Internet access provider.

Andrew Kantor: There are a lot of big, national providers out there and even more small, local providers.

Eric Berlin: The thing about the local providers is they tend to be cheaper.

Andrew Kantor: Considerably cheaper.

Eric Berlin: The national providers generally charge an hourly rate, with maybe the first 20 hours free, and then after that it's \$1.50 an hour or something like that. That may be fine for you if 20 hours a month seems like a whole lot of time; [in that case] you might want to go with a national provider. They also provide phone numbers from all around the country.

Andrew Kantor: So if you travel a lot and you want to keep connecting, there's an alternate number you can use, an alternate number in Boston, in New York, in San Jose, in Chicago. You can always find numbers and that's kind of useful if you're doing that.

Eric Berlin: They'll also hold your hand if you need it. They have tech support.

Andrew Kantor: Many local providers have tech support, but not 24 hours and it's not quite as good. Local providers give you much more personal service, where you can talk to Johnny and say, "hey, look, I'm having a problem," and he'll help you out. He knows you by name.

[With the national providers] it's kind of like shopping in a major supermarket; hey, it's really good, but the grocer doesn't know you. The difference, of course, in that analogy is that local providers are usually much less expensive than national providers. National providers have

to pay for a major network they're running, and for all these tech support people, etc. Local providers do not. They are usually a small operation and they're usually, in most cases, very good. I always recommend going with a small local provider rather than a national one.

Eric Berlin: You do have to configure your software. Your software comes preconfigured for a national provider, but you're going to have to do the manual configuring for a local provider. That sounds scary, but it's really not. All the software will ask for the same different chains of numbers; your provider will give you those numbers and all you have to do is fill them into the right blanks. But it is an extra step that you have to take. It can be a little intimidating.

Andrew Kantor: You call the provider. You say, "hi, I'm a local mom-and-pop shop. I've got *Internet in a Box*. I've got *Netshark*. I want you to connect me. What do I do?" They'll say, "okay, on this screen, type this, this, and this." It's really very simple.

With the national providers you look through a list, you start your software, and it asks which provider you want to connect to. Something like *Internet Chameleon* actually gives you a little screen that tells you how much they charge and all this other information, and boom — it does everything for you. It's a one-time advantage because you only have to configure it once, but it's nice. If you're really scared, go with a national provider.

You can always switch. That's another thing. It's the same Internet, so if you use *NETCOM* today you can switch to a local "BostonNet" tomorrow. It doesn't matter, it's the same Internet.

As I was saying, you can always choose another provider. Many providers provide software as well, even local ones. They'll say, "oh, we've got a collection of freeware that we've put on a disk. We'll send it to you and we'll tell you how to hook it up." It's often as good and often better than the stuff that large national companies will give you.

Companies like *NETCOM* are out on the show floor, and they have their own [software]. It's called *NetCruiser*. It's their own software, and it can only work with *NETCOM*. I believe now you can use other software, but at one point you could only use their software with *NETCOM*. They gave you the Internet, but you had to use what they provided you.

Other companies also do that. *PSI* is another big national provider, and they give you their software. So both local and large often will give you what you need.

Let's talk about cost. Just like buying apples varies from store to store, from big chains to little chains to local people to stands on the street, Internet access varies from provider to provider and costs anywhere from \$5 to \$10 a month to \$50 a month, and anywhere from \$0 per hour — it's called a flat rate — to a couple of dollars per hour [for additional time]. You have to shop around.

A nice thing about being in a major city is that there are usually several providers in the area, and you can call them. There are ways of getting lists of providers. In the *Elements* that you've got it tells you how to get a list of providers. You can look through the list and call and ask, how much do you charge, how much do you charge, how much do you charge, and decide what's best for you.

This is important and we always get questions about this. Whatever you pay your provider is your only cost for using the Internet. If you pay your provider \$15 per month plus \$2 an hour, that is your only cost for using the Internet — meaning you can send a million e-mail messages to your friends all over Europe and Asia, you can get information from computers in every continent, you can spend hours and hours a day on it, whatever your provider charges — and that's it [as far as the cost].

If you send e-mail to Japan you're not paying long distance phone charges. If it takes two seconds and your provider charges \$5 an hour — you do the math. You're paying a fraction of

a cent to send a message. Whatever you pay your provider is your only cost for using the Internet.

Now, when you're on the Internet, you may bump into things that say, "if you want to do this, you have to give a credit card number." I mean, they have for-fee services out there and I'm not talking about that, I'm talking about the things we're going to talk about today — using the WorldWide Web, using UseNet News, using e-mail. Whatever you pay your provider is it. And people always say, "but if I'm going to spend an hour on that computer in Sweden, I'm not paying long distance?" No. If you have a flat rate provider like I do, \$35 a month, I can do anything I want and it costs me \$35 a month, period.

It's very important. Also, the cost of the phone call to your provider — hopefully it's a local call and it's like three cents and that's it, but not counting that, that's all you pay. That's very important.

Andrew Kantor: There are so many providers that will charge you extra, but they'll give you an 800-number and they'll bill you \$5 an hour or something like that. CompuServe, I know, does it, and some other companies do, so there are providers that do that.

Eric Berlin: You'll have to do the math, since it turns out you're paying for the 800 service. You'll have to figure out whether that's cheaper than making a long distance call to somewhere.

M: Is it safe to put your credit card number for billing?

Andrew Kantor: Yes, and we're going to talk about that later. We'll talk about security issues. Most of these providers, when you call them, you'll say, "hi, I want to be connected to the Internet. I have this software." They'll say, "okay, here's the information. Here's your name, here's your password. What's your credit card number?" And you rattle off your credit card number. That's fine, you do it over the phone.

Some will let you do it over the Internet itself. Not too many, because they figure you're not on the Internet if you need a provider. But it is very safe to send your credit card number over the Internet. We'll talk about that when we talk about commerce and things like that.

[Let's talk about] on-line service. People say, "I've got America Online, aren't I connected to the Internet?" Well, kind of, but not really. You're also paying through the nose. CompuServe is an odd little exception right now, and the others are going to become odd little exceptions.

First of all, they're not true Internet providers. They are on the Internet and you can use their computer and get the information that they get off the Internet, but they're not really Internet access providers. You're not connected directly to the Internet.

When you connect to the Internet the way we're going to show you we are, you are on the Internet. You are getting information directly from other computers. Your computer is talking to these computers all over the world. If you're using CompuServe, Prodigy, AOL, you're just talking to their computer. It's not a big difference, and their computer is talking to the Internet; it's not a big difference, but it's an important one.

These providers are much, much, much more expensive. America Online, especially, is phenomenally expensive. You get five free hours — for \$10 a month you get five free hours. That's \$2 an hour, and that's not that cheap. Then it's \$2 an hour [additional]. So America Online is \$2 an hour, CompuServe is a little less, Prodigy is also a little less, but you're paying through the nose.

You're paying through the nose because they offer their own stuff. They may offer you software, they offer you tech support, and they offer their own content. If you want to get

Grolier's Encyclopedia you can only find it on CompuServe. If you want to get *TV Guide*, they're not on the Internet right now, you can only get them on Prodigy. These services have their own content, and they've organized that content really well. They've made it really easy to use, and you are paying for that.

If you want to use the content, if you want to have access to the access of Prodigy, America Online and CompuServe, then by all means, pay for it. If you want access directly to the Internet and everything that's out there, which I think is a lot better, then why pay these people for their content? Why pay for something you don't need? It's like buying a car with all sorts of options that you don't really want, but it comes with it. This is the same thing, where this stuff comes with all sorts of information that you probably don't need.

[Tape change]

Andrew Kantor: If you want to access the Internet and you're an America Online subscriber, if you want to access the WorldWide Web, you must use their WorldWide Web software. If you're connected directly to the Internet you can use any of a dozen packages, things like *Netscape* and *Mosaic*, which you might have heard of. You can't use those with America Online or Prodigy.

CompuServe is different because CompuServe now has its own Internet division, so CompuServe will actually give you a true Internet connection as a separate kind of service. You're still paying full CompuServe rates, but it's a direct connection to the Internet and you use your own software. So that's why I said it's kind of a little exception to the rule right now.

Eric Berlin: In time everybody will.

Andrew Kantor: Yes. Prodigy and America Online are both aiming in that direction.

W: [inaudible]

Andrew Kantor: Okay. Her company uses CompuServe. Does that limit her to what she can get on the Internet? No, not exactly. Of course you would pick CompuServe, the tough one to explain. If you have CompuServe, you have whatever CompuServe information manager on your desk. That's what your company uses and you can use all their tools, all their Internet tools — [which is a package called] *Go Internet*. They have a bunch of tools. So you can get the same thing, although you're kind of stuck with their software which isn't all that great. But with CompuServe you can also use regular Internet software. You have to call them up and they'll explain to you how to set it up to use regular Internet software over CompuServe.

If you have America Online, if that's what your company has or that's what you have at home, you can use the Internet. You can do all the things we're going to do, although the software isn't quite as good. So you can do all this stuff because they all have access to the Internet, but it's not as easy with an on-line service as it is when you're directly connected to the Internet. For one thing, you just don't have the choice of software. There's really good Internet software out there, and the on-line services are not quite caught up to the quality of software.

Microsoft Network came out, but first they said, "We're going to replace the Internet. We're going to be bigger than the Internet." I have yet to see the Microsoft Network show. Someday it will be there. Microsoft Network works just like the others, except much smaller; and they offer, again, Internet access to some extent. Use their tools — it's just the same. I

don't mention it because they're so small. There's also Genie and Delphi; there are other on-line services besides the Big Three.

Eric Berlin: Let's not forget eWorld.

Andrew Kantor: I'm sorry, [there's also] Apple's eWorld. They all offer Internet connectivity using their tools, so they're all doing basically the same thing. Whatever I just said applies to all of these services, and there are a lot of them.

Small local bulletin boards also apply the same way.

Eric Berlin: At this point I'd like to take a five-minute coffee break. We do have our dial-up connection and we want to test it before the dial-up man leaves.

Andrew Kantor: When we come back we're going to talk more about connecting to the Internet and what tools are available. We're going to explain what people are doing on the Internet — electronic mail, UseNet News and the WorldWide Web. We'll be back in about five or ten minutes.

[Coffee break]

Andrew Kantor: [Let's talk more about Internet access providers]. Service is what generally differentiates them, service and price. What are the prices? Do they have different pricing plans? Will they help you get set up? Will they offer to put your information on the Internet? How much do they charge to put your information up there? They used to be called "Internet access providers." Now they do all this other stuff and they've become "Internet service providers," and that's really the difference.

M: [inaudible]

Andrew Kantor: Is the *New York Times* only on America Online? No, they have information on the Internet also. They have an eight-page edition, including the crossword puzzle, with the headlines and major stories that are out on the Internet. Right now they have a deal with America Online, but that's probably going to change because they have to pay America Online to be there. Why should they bother paying them when you can just put a computer on the Internet? And it's a lot less expensive.

Eric Berlin: It's all going to change. The on-line service structure is going to start crumbling because it's cheaper and because you reach more people by going onto the Internet instead.

Andrew Kantor: It's cheaper for a company to put information on the Internet, and cheaper for people to access the Internet than the on-line services.

Eric Berlin: How about we begin? Are there any other questions on connectivity? We did kind of go over that a little quickly.

Andrew Kantor: Everyone have this general picture of the Internet? It's this big bunch of computers, each computer has a bunch of different people who use it, each computer has a bunch of different information these people have put on it, and there are computers out there that you can use to call Internet access providers to connect and get information and stuff from

these other computers. And that's what we're about to talk about, how to do that. But it's just this big bunch of computers, and it's important.

Eric Berlin: [Let's] move on. People basically do two things, and only two things, on the Internet: they talk to each other and they find information. They communicate and they go out and find some piece of information that they want and retrieve it to their own computer. That's pretty much it. These break down into several other things, of course, but that is the sum total of what you can do on the Internet: communicate and find information.

Communication breaks down into three things: electronic mail, or e-mail — do all of you have e-mail in your offices? How many people here use e-mail in some way on a daily basis?

Andrew Kantor: How many people don't? Okay, good. At least a few of you.

Eric Berlin: So we'll go over that, and UseNet News, which is the giant bulletin board of the Internet, and Internet Relay Chat, which is a kind of fun little diversion that we'll just briefly tell you about.

We'll start off with e-mail, which is easily the most popular form of communication on the Internet. Everybody on the Internet has an e-mail address, and every e-mail address follows the exact same format.

Andrew Kantor: Let's talk about e-mail addresses first.

Eric Berlin: Going back to this diagram for a second, imagine now that every single one of these places — the computer at these places — has a name.

Andrew Kantor: This isn't the textbook company's computer. I mean, they may call it that or they may call it "Orville" for all I know, but in terms of the Internet it has a specific name that other computers that are connected can recognize.

Eric Berlin: So shoes becomes shoes.com. A college becomes college.edu. Every computer on the Internet has a name. Every access provider also has a name. I connect to an access provider called PANIX, a commercial access provider, and therefore the name of their computer is panix.com — C-O-M, which stands for a commercial site on the Internet.

Andrew Kantor: Anything with a ".com" means it's a company, it's a corporation, like the shoe company or the leather company. E-D-U means — well, you can figure this much out. There's also G-O-V for government computers and M-I-L for military computers.

Eric Berlin: O-R-G is for non-profit organizations.

Andrew Kantor: O-R-G, right. Computers outside the United States end in their country code, so computers in the United Kingdom end in UK. IL is for Israel, ES for Spain, etc. LI is for Liechtenstein.

The second part is determined — the .com or .edu or whatever — is determined by what kind of organization you are. If you're a commercial organization you're going to be .com. The first part is the people, and the company decides; as long as no one else is using shoes.com, the people at the shoe company can call their computer shoes.com. I mentioned the Internet Network Information Center, the InterNIC. They're in charge of making sure that there's no conflict of addresses so things don't get confused.

Eric Berlin: Technical things you don't have to remember. This is called a "domain name."

Andrew Kantor: Yes, domain name. Now, there's always a big flap about domain names. It's always good to have a good domain name. The good ones are all gone already, pretty much. My company, *Internet World*, is iw.com. It's very hard to get a two-letter domain name because they're so popular, because they're so easy. The Princeton Review, the SAT preparation company, registered one of their computers as kaplan.com. Well, needless to say, their competitor, Stanley Kaplan, was a little upset that the Princeton Review had taken this name that they really wanted, and there was a whole legal flap about it. But things like that do happen.

Eric Berlin: The InterNIC says you must have the legal right to use a domain name before they will assign it to you, but once upon a time you could register any domain name you wanted. For a brief period of time people were registering domain names left and right — at&t.com, mcdonalds.com, pepsi.com — in hopes of selling that domain name for big bucks to the actual companies.

Andrew Kantor: It worked at least once, for the kid who registered mcdonalds.com. I don't know if his name was McDonald or not, but he got mcdonalds.com and McDonalds tried to sue him and take it away and they couldn't, and they ended up paying him an undisclosed sum to have mcdonalds.com instead of mcd.com.

Anyway, all these computers have names, called domains. All these computers have names. That's what I want to tell you.

Now we're going to talk about e-mail addresses.

Eric Berlin: I get service from an Internet access provider, and their computer is called PANIX — panix.com. This is no longer the first example, however.

Andrew Kantor: Sorry, I changed this. Incidentally, I've taken your name off. Why don't we go back to mine? My company is *Internet World*. As I said, my company computer's name is iw.com. My house at home, where I live, is 676 Monroe Turnpike. That is the name of the house; iw.com is the name of my computer. You write to me at Andrew Kantor, 676 Monroe Turnpike, or you write to me at ak@iw.com. The first part is my name, the second part is the name of the computer where I am.

Eric Berlin: Just as there can't be a second computer called iw.com, there cannot be a second person with an e-mail address that's ak@iw.com. Imagine if you lived in a place where everyone in your family was named George, like George Foreman. Well, who does it go to in that house? It's the same thing. To avoid confusion, there's only one ak@iw.com.

Sometimes computer names are a little longer; at panix.com the company may have several computers hooked together. There's mail_panix.com and info@panix.com, [which are] different computers.

Eric gets his mail at eric@mail.panix.com, so that's where you can write to him. Actually, you can also write to him at eric@panix.com. All e-mail addresses have the "@" sign in them. So his address is a little bit longer than mine might be.

My friend, Tanya, who is out on the show floor someplace, used to be at Emory University. She had this monster address: emoryl.edu. Well, the computer center has their own computers, and there's a specific UNIX computer within it, and that's where she got her mail, so she was tmazaro@emoryl.edu. So names can be longer.

M: What does PANIX stand for?

Andrew Kantor: Public Access UNIX.

Eric Berlin: Aren't you glad you asked?

Andrew Kantor: Your life is enriched by that little tidbit of information.

Eric Berlin: Please also notice the dots in the e-mail address that separate words. There cannot be spaces in an e-mail address; you might sometimes see an underscore thing, but you cannot have spaces in the e-mail address.

Andrew Kantor: They're also always lower case. People can write them in upper case, it really doesn't matter, but traditionally Internet e-mail addresses are always all lowercase.

Sometimes they're even longer, like my old boss at *PC Magazine*. This was her address: gschaefer%editorial%pcmag@mci_mail.com. If you ask someone their mailing address and you say, "I want to send you something, what's your mailing address?" And they say, "my address is 123 Main Street, Suite 16, Cube 14, Mail Stop 8..." I mean, you write it all down, and it's kind of annoying, but you trust them. That's their postal mail address. [This is the] same thing; some e-mail addresses are longer, some are shorter. They all usually go to the right place.

W: [inaudible]

Andrew Kantor: The question is, who makes sure that no one else has these domain names? The InterNIC does. In other words, you can call your computer anything you want, but the InterNIC will register it and tell all the other computers on the Internet that you are jane.com. So you can call yourself jane.com, but if someone else has it you're never going to get any messages and information won't get to you. There's a whole registration process you have to go through.

The most famous e-mail address is president@whitehouse.gov. That is Bill Clinton's e-mail address. It is for real; you can write to him, or rather to Steven something...

Eric Berlin: Steven Horn, I think his name is.

Andrew Kantor: Steven Horn. He's the guy who actually answers the President's e-mail.

Eric Berlin: When you write to the e-mail [address], you get an automatic response back, "Hi, we've read your e-mail — yeah, right — and if it's important, we'll pass it on to the President himself."

Andrew Kantor: Thank you for your question about the deficit. The president will write to you soon.

Eric Berlin: If the president does write back, he doesn't do it by e-mail actually, he does it by "snail-mail," as we call it.

Andrew Kantor: But he does write back, because I came home and found a letter waiting for me one day from the Department of Justice, which scared the heck out of me. It was just a

response — “you wrote an inquiry to the President...” and they responded. So it was kind of weird; they do write back. It’s just as effective as writing a paper letter. I mean, it gets in a pile and maybe he answers it.

Eric Berlin: E-mail is basically the same thing as postal mail except you don’t have to run it down to the corner mailbox and wait three days; you just basically — as you’ll see soon — press “send,” and three seconds later it will be in the recipient’s mailbox. By the way, it’s free. Once you’re connected to the Internet you can send as much e-mail as you want to as many places as you want. It’s not more expensive to send it overseas, and it’s not expensive to send files. We’ll be showing you how to send files.

Andrew Kantor: CompuServe and Prodigy at one point did charge per e-mail message and per size, and MCI nailed it as well, but those are gone now. Those are the old days — that is, 1994. Things move quickly; if you blink you might miss something.

Eric Berlin: You just basically plug in the right address, put in your message and you click on “send.” We’ll show you this in a moment.

Andrew Kantor: You, as an individual, can register a domain name, but you have to tell the InterNIC not only what name you want, but what computer. So I can register kantor.com and I have to tell the InterNIC that anything that’s destined for kantor.com should come to this computer. Now, that computer I send it to can be my Internet access provider, and many access providers will say, “oh, we’re panix.com, but if you want to be kantor.com, for \$20 a month we will handle mail to kantor.com.”

So I tell the InterNIC, “Hi, I’m Andrew Kantor, I’m registering kantor.com, and panix.com in New York will be handling my e-mail. Set me up.” From then on, that’s all it takes. The InterNIC tells the rest of the Internet, over the course of a couple of days, that anything to kantor.com comes to me.

For instance, in my company we’ve registered a whole bunch of domain names for various reasons: iw.com, mecklermedia.com, webweek.com, bigcorp.com. You can write to me at ak@bigcorp.com because whenever I write, I always give an example, bigcorp.com, and people were writing and complaining that they weren’t getting anything. So now you can write there. So you can register these and then you have to find a provider and say, “we’ve registered these, handle this for us.” You talk to an Internet access provider and then you can use those domain names.

Eric Berlin: We’re in a period now where people are going bananas with extreme domain names. Holiday Inn registered holidayinn.com and holiday-inn.com, and some other things. Just holiday.com, I believe they got, too.

Andrew Kantor: Every product, any name. Velveeta.com — every Kraft product you can name is a domain name owned by Kraft. They went nuts; they registered everything. Now it costs, I think, \$100 for two years for a first-time registration. It used to be free, but it got a little much for them to handle, so it’s \$50 a year and you have to pay for two years.

M: [inaudible]

Andrew Kantor: There is an address, and they are on the Internet. There’s a 619 phone number, so if you want you can call information in 619 and ask for the Internet Network

Information Center. I don't remember the number anymore. But they don't like phone calls, because they get calls like "how do I advertise on the Internet?" They get all those calls at the InterNIC. I know because I get them, too.

M: [inaudible]

Andrew Kantor: InterNIC. Internet Network Information Center.

Eric Berlin: Getting back to e-mail here... You can send to several people as easily as you can send to one just by plugging in as many e-mail addresses as you want.

And finally, the last and most wonderful use of the e-mail is that you can join a mailing list, which is akin to a magazine subscription. Basically, when you subscribe to a mailing list you're getting in on an ongoing discussion on a topic, like the gardening lists that some people run.

Andrew Kantor: You essentially write to the person who runs this list — and we'll tell you how to find him — but you write to the person and say, "I want to be on this list," and they say, "Okay." That's all there is to it.

Eric Berlin: Then as soon as somebody sends a message to that list, everybody who is on that list will get it. Then you can un-subscribe from that list later on.

Andrew Kantor: If you send a message to the list, then the 500 other people who are subscribers also get that message. It's kind of an automatic re-mailer.

Eric Berlin: Let's show *Eudora*.

Andrew Kantor: That little blue dot in the right corner means it's time to show you *Eudora*. The e-mail program that we're using is called *Eudora*. There's a freeware version on the Internet, as well as a commercial version sold by a company called QualCom. *Eudora* is — and I've tested them all — the best e-mail program out there. They have a Macintosh and Windows version. They're wonderful.

Eric Berlin: This is all my old e-mail.

Andrew Kantor: If you look on the top, it says, "Eudora In." This is his in-box and these are all the messages he has received. This is who it's from, and we see the names: Dan Berlin, his brother, Lisa, and there's me. [We also see] when it was originally sent, the time and date, how long the message is and the subject. The big difference between Internet e-mail and postal mail is that postal mail does not have a subject, so the envelope does not read "major bill" or "annoying advertisement."

Eric Berlin: I use e-mail quite a bit. It's so much more convenient, sometimes even more convenient than the telephone. I communicated with my brother, who is here in Boston, and we had to e-mail back and forth to each other as to how we are possibly going to meet.

Andrew Kantor: If you're staying at a hotel, you know how expensive it is to make calls from your hotel room. So why do that when you can just do e-mail?

Eric Berlin: Andrew lives in Connecticut and I live in New York City, and together we write a column for *Internet World* magazine. We see each other about once every six months or so, but we are constantly e-mailing the column back and forth, trading ideas, sending each other ideas and putting the column together each month. This is all happening over e-mail.

Andrew Kantor: Let's demonstrate.

Eric Berlin: Let's send just a plain old message.

Andrew Kantor: Click on "New Message." Well, it's pretty obvious that it's already from Eric and the computer knows him.

Eric Berlin: Send it to you.

Andrew Kantor: Okay.

Eric Berlin: Actually, just one other thing; I've set up some nicknames or aliases in *Eudora* and I don't even have to put in ak@iw.com. If I simply put in AK, *Eudora* knows who I'm talking about and will send it immediately.

Andrew Kantor: It's just a little shortcut.

Eric Berlin: It's a very good thing for an e-mail program to have since not everybody has such a wonderful e-mail address as he has.

Andrew Kantor: Let's move on. He gives it a subject. Then he can send copies to other people, and he can attach a file so he can say, "here is this great game I've got."

Eric Berlin: I can send a file simply by choosing the right thing.

Andrew Kantor: Attach a document.

Eric Berlin: It will call up my file manager and ask me, "okay, what do you want to send?" And it's all transparent. It will do its encoding, it will send it out over the Internet, and his mail reader will decode it. It's all transparent.

Andrew Kantor: You notice the signature up there? That's a file that Eric has created that is tacked on to the end of every message he sends. It probably says something like, "Eric Berlin, freelance writer and playwright," or something like that.

Eric Berlin: Actually, I haven't created it, but I could if I wanted to.

Andrew Kantor: Right. And it will be attached automatically to the end of it. He clicks "Send" and — we were disconnected from the Internet, so what it's doing is it's automatically dialing the Internet again. It says, "Oh, you're not connected. I'm going to dial your access provider."

Eric Berlin: And... It's busy. Let's take your questions.

M: I have a question about attaching. I'm having trouble trying to send attachments over the Internet.

Andrew Kantor: Who connects you to the Internet?

M: I don't know. I work for Lotus, so... [inaudible]

Andrew Kantor: When you send a file it has to be attached to a message in a certain way. There are three major "computer-eze" schemes for attaching a binary file — a program, a picture, whatever — or a word processing document to a message. They are called — this isn't that important — Mime, Binhex and UUEncoding. Most e-mail programs nowadays support all of these. *Eudora* supports Mime, Binhex and UUEncoding, but some do not. So if you use Mime to attach your message and you send it to someone who's on a Macintosh, many Macintosh programs do not read Mime, they read Binhex and they'll just get gibberish. So at my company we always use Binhex because more people use Binhex, but Mime is better.

Did we connect?

Eric Berlin: Yes. It's contacting now.

Andrew Kantor: Here we go, and we're watching the progress of the message. You don't have to see that. I'll have it in about five seconds; it goes from this computer to Eric's provider in New York and then to my provider, my company in Connecticut, and if I check it from my hotel room later it comes to me. Boom — just a matter of seconds.

I've never had messages lost; it's very tough to lose messages. It happens as rarely as postal mail gets lost, which is once in awhile, and you hear about this probably less rarely. The Internet is designed to withstand a nuclear war; the post office is designed to withstand a postal workers strike, which is more severe.

M: [inaudible]

Andrew Kantor: If there's something wrong with my address, if he sends it to, [for example], andrewkant@iw.com, it will bounce back and it will say there is no one by that name at iw.com. It's gone from the network and he'll get a message back saying that it could not be delivered.

Eric Berlin: If there's something wrong with the iw.com computer, that message will wait in the next computer on down the line and wait for that computer to come back up, and then it will send it through.

Andrew Kantor: It travels from his computer along to mine.

Eric Berlin: It's a remarkable little system.

M: Are domain names unique [inaudible]?

Andrew Kantor: Absolutely unique. There is only one panix.com on the Internet.

There can be Erics all over the place. There can be millions of Erics. He's eric@panix.com and eric@iw.com. That's the basics of e-mail.

M: [inaudible]

Andrew Kantor: That's a function of the software, whether you get copies of the messages you send. Eudora can save copies. Most packages will ask if you want to save a copy in an outbox; that's just a function of the software.

M: [inaudible]

Andrew Kantor: Yes. I have hundreds of folders, and you can categorize it. But again, that's not an Internet thing, that's a software thing. Some programs do more than others.

Eric Berlin: Here are all my mailboxes here. Every mail message I get in — in theory, obviously — I put into the correct mailbox for later digestion.

M: [inaudible]

Andrew Kantor: How many characters can you have in your domain? That's a very good question. Some computers can't handle some [longer names]. In general, I think 16 is the limit, although some can handle 32 and supposedly 64. I've never seen — longer names are bad because people cannot remember them. My company has worldwideweek.com. I mean, no one is going to bother typing all that in, so I think 16 is the limit you should keep in mind.

M: Can they contain numbers?

Andrew Kantor: It can be anything you want. A company has — micro0ft.com is out there. So you can have numbers and letters if you want, [like] century21.com.

Eric Berlin: We must move on.

Andrew Kantor: Unless you don't want lunch. Questions? How do you get someone's address? Well, how do you get someone's phone number? You ask them. How do you get someone's postal address? You ask them. I can get someone's phone number by calling information, you might say; can't I do that on the Internet? No.

If you meet somebody on an airplane, if you're traveling from New York to Los Angeles and you know his name is John Smith or Mary Doe and you get off the plane and think, "Oh, wow, I want to give her a call," or "I want to give him a call," you think "Well, I'll just look up Mary Doe. I'll just call information." Well, what city?

Same thing with the Internet. There are seven million computers out there, and, let's say 5,000 companies that provide Internet access, just to give a real low number. Which one of those 5,000 are you going to look for this person? Which of those seven million computers is used by this person you met?

The only way to get e-mail addresses is to ask them, to look on their business cards to see if they advertise it, the same way you get someone's phone number. How do you get IBM's phone number? Well, you'll read an ad or you'll see something in a magazine. Same thing with e-mail addresses; it's really no different.

Unsolicited e-mail happens. People say, "Oh, you're a member of the gardening mailing list, and I sell bulbs so I'm going to send you mail advertising this." Does this happen? Yes. Do people like it? No. What are the consequences? Well, chances are that people won't buy your bulbs, and they can do nasty things and complain to your Internet provider. It's generally a no-no. It violates Internet etiquette, or "netiquette."

Eric Berlin: There are other ways to advertise, and we will be talking about that.

Andrew Kantor: There are proper ways to advertise and improper ways to advertise; but there's also unsolicited e-mail. I get tons of it just because of who I am and who I work for, but it is unsolicited e-mail. You'll probably get it once you start getting e-mail, [where you'll get things like] "I noticed you're a CompuServe subscriber," or "I notice you're on the Internet and wouldn't you like blah, blah, blah..." It happens.

Can someone read your e-mail? Well, your e-mail is going from place to place. It's going from your computer, to let's say, Los Angeles, and stopping at a bunch of computers along as it makes its way to Los Angeles. Can someone read it? Yes it can, just as somebody can tap into your telephone calls as your phone conversation makes its way across. You need to be a hacker to do it, for one, but let's say, yes, someone can intercept your e-mail and read it along the way. The government does this all the time. Many national security agencies routinely scan e-mail messages for certain things like terrorists or bombs or something like that.

Is it illegal? They're the government. They decide what's legal and illegal

Eric Berlin: In general, it is, yes.

Andrew Kantor: In general, it's not legal for them to do, it's illegal. They can't use it against you in court, necessarily; but that's another story. Can someone illegally tap in? Yes. If I'm a hacker and I'm on a computer somewhere between here and Los Angeles and I tap in, yes, I can get your e-mail.

What do you do about it? Well, you can encrypt your messages. There is software out there that lets you encode your message so only the person you intend to get it can get it and read it. The most popular and best one is called *PGP*, for "pretty good privacy." It's so good that the U.S. government tried to ban it because they couldn't crack it. That was a year ago; they probably still can't.

If Eric and I both have *PGP* we exchange, in person or somehow, what are called our "keys," and then when I want to write a message I can say to *PGP*, "encode this message so only Eric can read it." Then I send it to Eric and it asks for his password or pass phrase and it decodes it. So I can encode a message so only Eric can read it. We both have to have *PGP*, and it knows — you can intercept it — but it knows you're not Eric. You don't have his password, therefore you cannot read it. It's only encoded for him. So *PGP* is the way that many, many people encode messages if they want to keep it secret.

The other thing is, well, just like you wouldn't send a postcard with your credit card number, don't e-mail your credit card number without encrypting it. If I'm ordering flowers for my girlfriend, I know not to do it on the cordless phone because I hear other people's conversations on my cordless phone all the time. If I'm on that phone I wait until I can pick up a regular land-line phone before I do that.

Same thing with e-mail. It's possible, but it's fairly rare; in fact, I'd say it's very rare that anything comes of it, but yeah, technically, it's possible.

Eric Berlin: Let's move on to UseNet News. Imagine a supermarket in a small town; near the cash register in that supermarket is a big bulletin board divided up into eight or ten topics — baby-sitting, home repair, cars for sale, etc.

Andrew Kantor: You've all seen in the supermarkets where you can pick up the little cards and write baby-sitting and so forth. Imagine it's a corkboard instead.

Eric Berlin: So you come by, and you have a car for sale, so you take the little slip of paper that they provide and you write on it: "I'm selling a car. It's a Honda, call me at this number." You pop it up under "Cars For Sale," the correct category. Other people come to that supermarket and see that message.

Andrew Kantor: They're interested in cars, so they look in the car section.

Eric Berlin: They take a piece of paper and have something to say back to you. "How many miles does your car have?" writes one person, and they tack it up underneath your message. Another person comes by and says, "In what kind of condition is it? Is it okay? Are there dents?" And he tacks it up underneath that [other person's] message. You come back and you see your original message, and you see the messages that people have left. You are having a conversation across time. It's not real-time; people are leaving messages for each other.

The Internet has a similar system. There's your supermarket bulletin board.

Andrew Kantor: Imagine that you're walking through the supermarket and you're interested in furniture. You look at the furniture section of the supermarket bulletin board and you might see one message saying "For Sale," and you might see a little conversation going as people tack messages underneath the others.

Eric Berlin: I think you guys got the concept. The Internet has a system pretty much like that; but rather than eight or ten, there's something like 15,000 to 16,000 different topics going on.

Andrew Kantor: Imagine that supermarket bulletin board with 16,000 sections.

Eric Berlin: Obviously, nobody reads them all — you'd have to be a complete lunatic. So people subscribe to those newsgroups — that's what they're called — that interest them the most.

Andrew Kantor: Which is the equivalent of every day going to the supermarket and looking on the bulletin boards that interest you a lot. There's a thing about pet care; if you're interested in pet care you always go to the pet care section of the board to read it every day. That's what subscribing to a newsgroup is. It's telling your UseNet News software — we have e-mail software, we have UseNet News software — telling your UseNet News software, "every day, every time I check, tell me if there are any new messages in this section in this bulletin in this newsgroup."

You can also post a message, just like you could tack a note up to the corkboard of the supermarket. You can tell your computer, "Post this following message into the cats newsgroup, because I want to know about cats." So your message says, "I just got my first Siamese cat and he's wonderful," and you want you to put this up in the cats newsgroup.

Once it's up there, within a few minutes anybody else can read this message. Anybody else can come by who is interested in cats, just like anyone could walk by the supermarket and look at the cats board, or anyone else can say to their news reader, "Show me what messages are in the cats newsgroup. Oh, there's one from Andrew Kantor about his Siamese cat."

Eric Berlin: This, more than anything, is the Internet's interactive community. The WorldWide Web, which you've heard a lot about, which we will be discussing in great detail later, is the place to get a lot of information. But for the place to have discussions and arguments and debates and nice chats and whatever, this is the place, at UseNet News.

M: [inaudible]

Eric Berlin: What software do you need? Good question.

Andrew Kantor: We'll get to that in a second.

Eric Berlin: Every Internet suite, every Internet software that you buy will have a news reader in it.

Andrew Kantor: Or there are news readers available on-line, just like e-mail software. It comes with the package or you can get your own.

Eric Berlin: UseNet newsgroups — just like e-mail addresses, you'll see that these UseNet News groups are divided into hierarchies. They look a little bit like e-mail addresses, except there's no @ sign.

Andrew Kantor: Instead of baby-sitting and cars for sale, UseNet News has its own little language for naming these newsgroups.

Eric Berlin: Since there are 16,000 of them there has to be a way of dividing them up, so there are hierarchies. There's the "alt" hierarchy, which is a whole bunch of different newsgroups that don't seem to be pertinent anywhere else.

Andrew Kantor: This newsgroup might be called alt.fan.dave.barry. It's an alternative newsgroup for fans of Dave Barry, the humor columnist.

Eric Berlin: Just by glancing at it you could pretty much tell what it's all about.

Andrew Kantor: For instance comp.games.ibm.pc.action. That's a computer newsgroup for IBM PC action games.

Eric Berlin: You go on there and you ask questions. You get answers to those questions, and you ask about those answers, and you have discussions.

Andrew Kantor: Let's show them.

Eric Berlin: Let's do that.

Andrew Kantor: This is what UseNet News looks like. Eric is using a product called *Free Agent*, made by a company called Forte. It's a freeware, UseNet News software that's out there. He can just as easily use the software that comes with *Internet in a Box* or *Netshark* or whatever, but he's using *Free Agent*.

Eric Berlin: Here is a list of every single newsgroup. Now, there are 16,000 newsgroups out there, but remember that I get my access through a company called PANIX. PANIX does not necessarily get every single one of those 16,000 newsgroups. They get a great percentage of them, but there might be one or two frivolous ones that they don't think any of their users are

going to need, so they just don't bother with it. If I wanted it I could ask for it, but they get a large percentage of those newsgroups. Of those, I can subscribe to a subset.

Andrew Kantor: So this is the list that PANIX provides, all the newsgroups that are available; in other words, these will be bulletin boards at his local supermarket. Well, that's not entirely true because these are the newsgroups that he has access to, and all these users go to the entire Internet.

Eric Berlin: So the "alt" hierarchy is huge and weird.

Andrew Kantor: alt.fan.unabomber.

Eric Berlin: alt.fan.barney.dinosaur.die.die.die is in here.

Andrew Kantor: Let's get out of alt. for a little bit. So we're going to look at a newsgroup and we're going to say to our news reader software, "go onto the Internet and tell us what new messages are in the newsgroup called alt.home.repair." Control-F will let you search. alt.home.repair.

Eric Berlin: I subscribe to it. I can either click this button...

Andrew Kantor: Different news reader software use different ways of subscribing.

Eric Berlin: And now I can just go to — I don't have to look at this list all the time — I can go to my subscribed newsgroups.

Andrew Kantor: He's into games, puzzles, New York City singles — if you're not married.

Eric Berlin: So these are the things I subscribe to. I'm just going to get the messages at this moment; I'm just going to get the messages that are in alt.home.repair. Every message has a header that tells you what that message is about. So I'm going to go get the headers that are in that.

Andrew Kantor: The header is the same as a subject of an e-mail message.

Eric Berlin: You'll see that in just a moment. There are 354, so let's all have a little conversation while we wait.

Andrew Kantor: The problem is that we have a modem connection; if you're using, as most normal people do, a modem connection to the Internet, it's not going to be the fastest thing in the world. Unfortunately, that's what we had this guy hook up quickly before.

Modem connections, even 28.8 modem connections, are not the fastest thing around. It takes time, especially when you get to the Web where it takes time to load pictures and things like that. Hopefully we'll have the fast connection running.

Eric Berlin: It's running.

Andrew Kantor: Good. The speed of the connection will be the slowest thing between where you're getting this information and where you are. Often, in most cases, that slowest thing is

your modem because the Internet is fairly high-speed. It uses high-speed communications lines, it uses fiber-optics, it uses satellites; the bottleneck is almost always your modem. So that's why we say the faster the modem the better.

M: [inaudible]

Andrew Kantor: No. Rarely does that happen, because usually it gets to you quickly. The service provider at PANIX can be very busy, and thus take [a long time] to actually send it to him, but in general, once they start, it's not on that end.

M: What does "alt" stand for?

Eric Berlin: Alternative. "Rec" stands for recreation. These are the large hierarchies, alt for alternatives, rec for recreation, soc for social.

Andrew Kantor: PANIX has its own newsgroups.

M: [inaudible]

Andrew Kantor: Is there a code to use if you don't know what the meaning is?

Eric Berlin: Well, there are only so many of them. I mean, you'll see, like...

Andrew Kantor: 16,000 newsgroups. Well, you have to look at the names: [for example], alt.journalism.students — you can kind of figure out what that is; alt.ketchup; alt.jub.jub, I'm not so sure what that is.

But if you're looking for a newsgroup about architecture you can search this list for the word architecture; for instance, alt.landscape.architecture is right there. Generally, the name of the newsgroup tells you what it's about.

Eric Berlin: I can search with the keyword on this list and try to get somewhere.

In the second half of the tutorial we're going to be further demonstrating how to find specific pieces of information, and we're going to let you in on a couple more tricks; but for right now we just want to give the basic demonstration. So, back to alt.home.repair... This is the article list. This is what people are discussing in alt.home.repair right now. Here you can see when things were posted. It's all put together in chronological order here.

Andrew Kantor: Click on the word "Status," up there. These are messages people have posted, just like tacking up messages in the supermarket.

Eric Berlin: Here we see a number; that means that there are seven responses to this message that says "glowing light bulbs," whatever that means. I'm scrolling all the way down to the bottom. There are the more recent messages.

Andrew Kantor: Here, "warped door." So David Stevenson wrote a message called "warped door" and he wrote: "Does anyone have suggestions on how to straighten a warped wooden front door? It's an old-style solid wooden door." That's a question someone wrote.

Eric Berlin: And I can view the next article, which will be, God willing, a response. Perfect.

Andrew Kantor: Now this person, Jerry, wrote back. First, if you notice, he puts these little angle brackets up there, which indicates that's what David Stevenson wrote, and then he replies after that: "One way I can think of is to cut a notch in the door and insert a wedge. After you apply glue to it, this will force it to bend a little. You can make several such cuts. Of course, this can only be done if the door is painted."

So this is the basis of UseNet News.

Eric Berlin: In a nutshell.

Andrew Kantor: You write a message, you post to an appropriate newsgroup, and people write back to you. It's very simple.

UseNet News is hard to describe, but it's really very simple. You write a message, you post it; instead of sending an e-mail message to a person, you're posting to a newsgroup so anybody can see it, and then other people can reply.

[Let's talk about] problems with UseNet News.

Eric Berlin: The UseNet being such a huge community, there are many people that use UseNet News, and not all of them are nice. Would that they were, but they're not.

Andrew Kantor: Not all of them think the way you do, and not all of them share your religion, morality, or political views.

Eric Berlin: People get into debates, and people get into full-fledged arguments. Under the best of circumstances, they're at least talking about the issues. Under the worst of circumstances, they are insulting each other.

[Tape change]

Andrew Kantor: You like Rush Limbaugh, too, and that makes you even worse.

Eric Berlin: People get angry when they see a newsgroup that discusses homosexuality, and they go over there and they just [start writing things like] "You people are all dirty and..." This is an unprovoked "flame." This is what's known as a flame.

Andrew Kantor: A flame is a nasty message that you post to someone which kind of attacks who they are. I go to the cats newsgroup and I post a message, "I just got my first Siamese cat and he's wonderful." Someone may just say, "You idiot, Siamese cats are ugly and they're stupid and they smell bad and you're a jerk for liking them." He may write this. I may write back and say, "I'm a jerk?! Well, you're a —!" You get the picture.

Eric Berlin: Welcome to the flame war.

Andrew Kantor: Many people get involved. Flame wars take place in newsgroups like the political newsgroups, like alt.fan.rush.limbaugh. Or talk on abortion, that's a fun place to go.

Any issue you can imagine. The death penalty, NAFTA; name an issue and there's a newsgroup about it, and the people are yelling and screaming at each other and being children.

M: [inaudible]

Andrew Kantor: I was hoping nobody would ask this. Yes, there are ways to start this. There's an involved process for creating a newsgroup; it involves getting people on the Internet to vote on it.

Eric Berlin: You can create your own newsgroup. The trick is, how do you get access providers like PANIX to take on that newsgroup? So people rely on a sort of a voting process which has evolved, and if it passes the vote then access providers say, "Oh, okay, we'll take that since there's so much support, we'll take on that newsgroup and we'll let our users see it."

Andrew Kantor: But there is a process and there are files on the Internet like "How to Get Your Newsgroup Created," and there are people who just create newsgroups left and right.

Eric Berlin: We don't have the time to go into that in tremendous detail. We will tell you where to get information for that, though.

Andrew Kantor: [There's a term called a] "spam." One good way to get yourself some flames — and flames are not regulated to UseNet, you can get yourself some flames in your e-mail box as well — one good way to get yourself flamed is to "spam." Spam means to post the same off-topic message to dozens, if not hundreds, of newsgroups. People tend to do this because they are advertising something. They are advertising boots in the bowling newsgroup.

Eric Berlin: Or fishing gear in the political newsgroup. People say, 'oh, there are millions of people on the Internet and I can post a message to UseNet News.' The prototypical example of this is — I'll run through this quick — the famous example is that of Kantor and Siegel.

Andrew Kantor: No relation.

Eric Berlin: They are two immigration lawyers out of Arizona.

Andrew Kantor: Scottsdale, Arizona.

Eric Berlin: They saw the UseNet and they saw 10,000 or 12,000 newsgroups and they saw an opportunity, and they posted the same message advertising their Green Card services, saying they'll help you get your Green Card. They posted the same message in every single newsgroup out there.

Andrew Kantor: So people came to the bowling newsgroup and saw a message for Green Card services and said, "this is a bad thing."

Eric Berlin: Their argument was, "well, immigrants just don't read the immigration newsgroup. They could be interested in bowling or whatever."

Andrew Kantor: And they said, "hey, it's not illegal, is it? We're allowed to do it — free speech. It's our right to post wherever we want."

Eric Berlin: The problem with this is — they're not without a small point — but the problem with this is that if everybody was allowed to post everywhere, then what is the point of a newsgroup hierarchy?

Andrew Kantor: Why have topics?

Eric Berlin: It's like opening up your regular mailbox and finding 16,000 pieces of junk mail, and one real letter and a bill.

Andrew Kantor: One bill, you're lucky.

Eric Berlin: If you go into rec.bowling and you see hundreds and hundreds of advertisements for things unrelated to bowling and only a few messages about bowling, well, then UseNet has basically come to a halt. So the UseNet community interrupted Kantor and Siegel's little plan.

Andrew Kantor: Because in order to sell their Green Card services they had to give little tidbits of information, like their phone number, their address, their fax number, and their e-mail address. People on the Internet took advantage of these little bits of information.

Eric Berlin: Well, their Internet access provider was shut down because of all the hate mail they received.

Andrew Kantor: That is no joke, because the provider's computer can only hold so much e-mail waiting for people to retrieve them. Eric's computer holds Eric's e-mail until he retrieves it. They got swamped and they had to shut down.

Eric Berlin: The UseNet community had their address. They received untold numbers of pizzas and magazine subscriptions, untold numbers of prank calls. And their fax number —

Andrew Kantor: I love this, please let me tell this one. I love this story. This is what they did in the fax machine... People faxed them. People took a piece of black paper, construction paper, taped it into a loop and faxed it to them. Now, on your end, your fax is just scanning this paper, and what happens to their toner cartridge on that end as it just churns out page after page of black paper? It blows out the toner. That's what they did to Kantor and Siegel.

Eric Berlin: What truly makes them unique is the fact that they remain unapologetic to this day.

Andrew Kantor: They wrote a book called *How to Make a Fortune on the Information Superhighway*.

Eric Berlin: They claimed that "well, we got hundreds of responses and made lots and lots of money." They claimed to have made \$100,000 in business from that initial spam, but I don't believe it for a second.

Andrew Kantor: They're out of business now. I haven't seen them around.

Eric Berlin: I haven't seen them around. They started a company that will allow you to spam. They will spam the Net for you. A ski resort in Colorado took advantage of them, and when I called that ski resort to find out what the result was they claimed that reservations went up over 200% over the course of 48 hours.

Andrew Kantor: Which is like, wow.

Eric Berlin: They were very impressed. But I'm wondering — suddenly, by seeing this message, people from all over the world are going to suddenly come to Colorado in the course of 48 hours? How many of those 200% are going to show up?

Andrew Kantor: Yeah. How many of those reservations are real and how many people are saying, "yeah, yeah, I'll make a reservation."

Eric Berlin: This is not how to advertise. As I said, we will be talking about how to a little bit later.

Andrew Kantor: And that was just their phone number and e-mail address and stuff they made available right now. There's a spam going on with magazine subscriptions — and I'm sure we're going to write about this in the magazine — where people on the Internet have found out the social security numbers, the job histories and all sorts of other information about the guy who's doing this spam and they're just posting it to the Internet.

Eric Berlin: Let's move on.

Andrew Kantor: Copyright violations. When *Star Trek Generations*, the movie, was coming out, a few months before it came out people found in the Star Trek newsgroups the entire script of the movie. I have a copy of it. Someone posted the entire script. Well, Paramount was kind of upset and they wrote to the newsgroup and said, "Please, we've worked very hard on this. We're trying to make an entertainment movie. Please don't put this script out there." They were asking nicely to remove it, and people did and the script kind of disappeared from that. Well, that was a good example.

Playboy centerfolds are routinely put up there because I guess they figure people can't actually go down to Barnes & Noble and buy it. That's a copyright violation.

The most famous right now is the Church of Scientology. Ex-members of the Church of Scientology posted information to the Internet about the Church, about what they do, about Xenu, the head of the Galactic Federation who — and this is true, [according to] the people who write *Dianetics* — Xenu came to earth millions of years ago trying to solve the overpopulation problems of his planet by bringing people to earth and chaining them to volcanoes and dropping hydrogen bombs on them.

Eric Berlin: Scientology calls this a copyrighted trade secret of their Church.

Andrew Kantor: This is not a joke, I am not kidding. This is what Scientology believes. One PR person said to me when I interviewed them, "Well, how would you like it if somebody posted your religion's top secrets?" And I had no reply. People in Scientology were very upset.

Now, as much fun as we can poke at them, talking about Xenu and all the stuff they're worried about, they do have a point. If you're a company, if you're Coca-Cola and the formula for Coca-Cola gets on the Internet — I mean, there are trade secrets and copyright violations that come up all the time.

What can you do about it? Very little, because information spreads so fast it's often hard to figure out who posted it first. People can post anonymously and it's a whole legal wrangle to try to find out who they are. There's not a lot you can do. Copyright violations are rampant. Songs and excerpts from books and all sorts of stuff are always on there, and scripts for Star Trek and the stuff about Scientology.

Eric Berlin: The best thing to do about it, since the best source of information is the people who created the information in the first place — *Playboy* beat those people that would scan centerfolds and post them on the Internet. *Playboy* beat them to the punch by opening up their own site and offering the centerfolds themselves and selling advertising on those pages to generate revenue for themselves.

Andrew Kantor: Which leads us to the problem of dirty pictures. UseNet people routinely post pictures — I mean, you can scan in a *Playboy* centerfold or you can take a picture of your girlfriend or boyfriend and put it up there, and people do this all the time. Some people think that UseNet News is just full of this horrible pornography. It's not really a problem.

Out of 16,000 newsgroups there are about 100 that are sex-related, and about half of those have pictures in them and about a quarter of the messages are actually pictures. Most of it is just talking about it, and things like how to make money fast and advertising bicycles and stuff like that.

Eric Berlin: We're not saying it's not out there. It is.

Andrew Kantor: There's pornography out there. You can go look in the alt.sex.bestiality newsgroup and there will be 100 messages in there and two will have to do with what I did with my gopher or my hamster or whatever. It's out there, but it's really not a problem. We put it in the list of problems to kind of deflate it.

Eric Berlin: If you want to solve the problem for your own family, even if the thought of this little amount bothers you — and I can't blame you if it does — we do not necessarily need government regulations on it. There is perfectly legitimate software out there [that can prevent this]. One is called *Surf Watch*, and one is called [Net Mammy].

Andrew Kantor: [There's also] *CyberSitter* and *Crossing Guard*.

Eric Berlin: You can put these on your computer and they come preconfigured with hundreds of pornography types that they can block. Somebody actually researched this, I guess.

Andrew Kantor: Tough job.

Eric Berlin: They're preconfigured with all the sites that you probably do not want your kids to go and see, and you can add in more as you hear about them or whatever.

Andrew Kantor: So if you don't want your kid to see alt.sex.bestiality, you install the software. If he tries to get in it will say, "sorry, you cannot access it." It's very simple.

Eric Berlin: It is not a Herculean task to avoid pornography. It just isn't.

Andrew Kantor: The other thing, of course, is that government regulation can't stop it because a lot of this stuff comes from outside the country, and in most other countries people just don't care about this. So when we say dirty pictures we're also talking about all the stuff that you don't like that is out there — and I'm guaranteeing you there's stuff you don't like out there. As a French person once said to me, "You can always find an American offended by something." And that's the truth. There's lots of stuff out there on UseNet that you won't like.

Eric Berlin: Questions about UseNet?

Andrew Kantor: No? Good!

Eric Berlin: [Then there's] Internet Relay Chat. Internet Relay Chat is the CB radio of the Internet. It is, as somebody said, in real-time. We're not really going to demonstrate this because there's not a whole lot happening there. All the colleges are on the Internet Relay Chat, so it becomes a huge frat party. It becomes — it's like 30,000 men trying to pick up five women.

Andrew Kantor: It's like CB radio mixed with a frat party.

Eric Berlin: When you go on, you join a channel.

Andrew Kantor: You use IRC, Internet Relay Chat software. You connect it and you get the list of channels that are available, a list of hundreds of channels.

Eric Berlin: Hundreds and hundreds of channels. You join one that is active. All channels have a little pound sign in front of it; so you join #theater and there are people there supposedly discussing theater and whatnot.

Andrew Kantor: There's "Star Trek" and "Sex" and "Melrose Place" and "Gardening."

Eric Berlin: Five minutes before the OJ verdict came in, there were hundreds and hundreds of people in the channel "OJ" on the IRC. It was quite a little Internet event.

You can go and play games with other people who are sitting at their computer at that time.

Andrew Kantor: As you type, as soon as you hit "enter," everyone else on that channel sees what you have typed in. That's how it works. It's kind of fun. It's a diversion. It's not a major Internet tool, but we like to mention it.

That's about it. When we get back, we're going to kind of put all this together and we're going to talk about information. We've been covering communication. We're going to talk about information on the Internet, getting it, and different ways of searching the Internet and making it a useful thing. Here we're giving you a toolbox; we want to tell you how to build a car with your toolbox.

Let's break for lunch now.

TUTORIALS INTERNET 102

SPEAKERS

Andrew Kantor

Senior Editor, *Internet World Magazine*

Eric Berlin

Contributing Editor, *Internet World Magazine*

Andrew Kantor: [You can find the December issue of *Internet World* on] newsstands; if you're a subscriber you'll be getting it pretty soon. We review all the suites, Windows, what's available for the Macintosh, we talk about what's coming up, just in case you want to check that out. In fact, the January issue is going to cover some things that came out after this issue went to press. So between December and January, you can find out everything you want to know about all the Internet access software.

Eric Berlin: In this second half, we're going to be talking about information on the Internet. We will be focusing on the WorldWide Web; although there are a couple of other lesser places to get information, and we'll be discussing those as well. After that, we're going to be talking about how to use the Internet as an integrated whole; how to use UseNet to find an e-mail address of a person that you want to talk to about a certain topic; using the WorldWide Web to get that information in the first place, etc. How to use the whole thing.

What we'd like from you guys — later on, we're going to be giving some examples on how to find a certain product or something — but we want to know how you want to use the Internet. You came in here saying, how can I use the Internet to do such and such? We're up to the challenge, we hope, and we want to hear some suggestions. We will use your examples for...

Andrew Kantor: If you say, I want to buy a car — how can the Internet help me to buy a car? Or my kid is into dinosaurs, how can the Internet help me? That kind of question. How can the Internet help me do — fill in the blank. Think about these.

Eric Berlin: We are completely unimaginative and we kept coming up with how do I buy such-and-such a product? Okay, how do I buy this product?

Andrew Kantor: We're actually very boring people when it comes down to it.

Eric Berlin: So we have to rely on you guys for our examples. But that's in the second half. So just start thinking about that now. In the meantime, information on the Internet.

Andrew Kantor: Information on the Internet. You've got seven million computers out there and you can bet your something or other —

Eric Berlin: Bottom dollars —

Andrew Kantor: — bottom dollars or your bottom yen that there's lots and lots of information. All these different people putting it out there. The question, is how do you get hold of it? Well, it's great that it's out there but it doesn't do me much good sitting on a computer in San Jose or Tokyo or France or whatever. It will never do you any good in a server in France because it's all in French, which is an interesting thing people talk about.

What is the language of the Internet? Is everything in English? Yes, most things on the Internet are in English simply because the United States, people in the United States make up more than half of the Internet. So everyone kind of realizes that if you want people to understand you, you've got to speak in English. Except the French, who continually hold out and put things up in French and nobody actually sees what's up there. This is true. You're supposed to kind of least snicker and then we're going to get in the mood for the next...

Eric Berlin: Oh, make a funny joke and then they'll laugh. Come on, let's go.

Andrew Kantor: So what's on the Internet. There are three forms of information out on the Internet. There are just plain old files. You have files in your computers. Your software, that's files. You have your budget, that's a file. Bad poetry, that's a file. There are Gopher menus, which are a text-based way of getting information from the Net. And there are WorldWide Web pages, which are probably the best-known thing. Incidentally, this is the most proper way to write "World-Wide Web." Spaces, hyphenated, how do you dot it. Although in the magazines we [don't] put a hyphen between the World and Wide because technically it's one word and a second word with three capital W's, but that's another story.

So, once upon a time, when there were, say, a hundred computers on the Internet and a couple of thousand people, at most, using it, it was easy to get a file. You would call up your friend who worked on the other computer because everyone who was on the Internet knew everybody else. It's kind of like living in a neighborhood. You just knew because these were all computer geeks and they all kind of knew one another and got together.

You would call Johnny at whatever institution he worked in and say, "Johnny, have you got that file on how to rebuild a transmission?" or something. And he would say, "Oh, sure" and he'd tell you it's on this computer in this directory — or this folder for you Mac people — and this is the name of the file. And you would say, "Great" and you would use your computer to connect to it in a variety of ways and get that file. That's how it worked. Word of mouth. You would call and ask somebody.

Well, that was great back then. But nowadays, with 20 or 30 million people on the Net and seven million computers and billions and billions of files, it's a little more difficult — although you can still call up people and say, "Hey, I understand you've got this file. Where is it? What machine?" They will tell you where it is and you can get the file using a process called "file transfer protocol," or FTP. You can still do that. It's a lot harder. But you know these files are out there.

Where are they? It's kind of like being in a library and knowing there's some information in some book and there's no card catalogue and the librarian is very busy right now. Where do you find this information? Oh, and the books aren't labeled either. The spines aren't labeled — the books are. That's what Internet is in terms of finding a particular file. It's not easy. There are search tools out there. One of them is called Archie, and Archie will let you search the files that are out on the Internet if you know a particular file name.

So let's say you wanted to rebuild a transmission for a 1978 Datsun B-210. Well, what's the file name? Would it be "transmission.doc"? Would it be "rebuildB210transmission"? If you don't know what the file name is, you cannot find it because you have nothing to search on. That's why finding particular files on the Internet is not the way people go about getting information.

Now, if you want a particular game, if you want a patch for software, an upgrade or piece of software, well, that's great. You want a particular file. But in general, you're not going to be looking for files on the Internet.

In cases where you are looking for files, you might see a message where people will talk about files. For a great list of recipes get the file "cooking.text" from ftp.bigcorp.com in the public directory.

Eric Berlin: You might see that on a newsgroup, you might have read it, and then you can just go and check it out yourself.

Andrew Kantor: In fact, in the magazine we print FTP sites for information. FTP, file transfer protocol, that means get the individual file, and all you need to know is the name of the computer, where it is, the name of the directory or folder, and the name of the file.

A shareware version of the software is at ftp.somewhere.com. That's the computer. The pub games directory and cardshark.exe. That's what you need. Again, people don't really get that unless you want a particular piece of software or a particular file. You're not going to use FTP. It's just kind of clunky. The reason being, you don't care about the file name. The file name is not important. You don't care what file contains the information you want.

You want the information. You want to know the population of Fiji. You want a complete list of light bulb jokes. You want to know how to rebuild the transmission of a 1978 Datsun B210 — you don't care what the file is called, you need the information. Because the Internet got bigger and bigger and people realized that, well, people want information, not particular files, systems were developed — culminating in the WorldWide Web — systems were developed to make it easier to find the files.

First was Archie to let you search for files and file names; but then came Gopher. Gopher was developed at the University of Minnesota, where the mascot is the gopher. Gopher gives you menus. You have e-mail software, UseNet news software, you have Gopher software. Gopher gives you menus.

People owned a computer. They had a lot of files on it, files of text-based information, because Gopher is, for the most part, text-based. But people didn't know their file names. So what do we do? We create a menu. We'll put a menu up there and it will say, do you want 1, this; 2, that; or 3, this. I want to know how to rebuild transmissions and you would choose what you wanted for a menu. So you had all these files in the basement. Then you have a menu to pick something and it would suck the file up out of the basement and give you the file you wanted.

General Motors may have Gopher information available on the Internet. You use your Gopher software, you tell your Gopher software, connect me to the General Motors computer, whatever the name is. You might see something like this:

1. Chevy Information/
2. Buick Information/
3. Olds Information/
4. Saturn Information/
5. Other Car Companies/

You say, I want Buick information. It ends in a slash, which means it leads to sub-menus. That's what Gopher looks like. You say, Gopher software, take me to General Motors. You see a list and you hit 2, Buick Information/ — and it might bring you to another menu that would say:

Choose:

1. For Gas Mileage/
2. For This Week's Recalls/
3. Models and Availability/

That kind of thing. Gopher just arranges all these files — these text files that these computers have — into a menu. So the files are still there. You can get the files individually or you can go through Gopher and see what's in them.

Gopher is old technology. Gopher is text-based and people are not text-based. We like visual things. Gopher was a good way of organizing some information, but it wasn't all that wonderful.

Eric Berlin: I would say that *Archie* is also becoming old technology. Both Gopher and *Archie* and FTP have been rolled into, not the WorldWide Web, but Web browsers, which we're about to show you will also allow you to look at Gopher menus and also allow you to transfer files.

Andrew Kantor: You no longer need separate software to do these things. It used to be you needed Gopher to do Gopher. You needed an FTP application to do FTP. Now it's all rolled into one.

Eric Berlin: So everything basically becomes the WorldWide Web.

Andrew Kantor: WorldWide Web — the way everybody's making information available. Nowadays, if you are putting information on the Internet — and if you remember from Part One, that means you are putting information on your computer, which is connected to the Internet — if you're putting information on the Internet, you're putting it on the WorldWide Web. There are a few people who are putting stuff in Gopher; very few, the US government is still lagging a little behind. But if you are putting on information and making it available to other people, you are putting it on the WorldWide Web. The WorldWide Web is part of the Internet.

The WorldWide Web is a publishing platform. You have, basically, only your computer; you can create pages of information. If I take my WorldWide Web software — it's called a browser — and I point it to someone's WorldWide Web site, I will see a page of the WorldWide Web. (We'll show you that in just a second.) On that page there can be formatted text that is bold and italic and big and small. You can put pictures, you can put animation, you can put sound. It's kind of like you can create your own magazine page on the WorldWide Web or series of pages on the WorldWide Web.

Every page has its own address, so I can say, oh, I'm going to advertise: I'm Sony Pictures and I just created a movie called *The Scarlet Letter*, whatever, and you can see information about this movie at this Web address. This is the address of the page and I would take my Web browser and point it to that page.

A page can have all sorts of things and that's why it's so big. Gopher just gave you text. The WorldWide Web gives you formatted text and pictures and graphics and all sorts of wonderful things. It makes everybody the publisher of a magazine and the writer of a magazine and the editor of a magazine. There are people now who have created their own on-line magazines, on-line newsletters, making information available on the WorldWide Web because it lets the creativity come out and make information available.

In the old days, you could put a file... I could write a poem, put it in a file and maybe somebody would take the trouble to download the file — find it and download it — but probably not. But now I can put it on my WorldWide Web page, so if someone comes to my Web page I can have all this information, whatever I want there. I can also, by the way, create links from my Web page to other people's Web pages. So I can say, I really like spaghetti and I can have a link so that if you select the word "spaghetti" with your mouse, it links you to the Ragu page where Ragu has information.

Now I can link to any public page, any page on the WorldWide Web and anyone can link to me if they want to. In fact, if you go to Internet World — our page is on the WorldWide Web — there are links to my page and I have links back to theirs.

So the WorldWide Web makes everybody a writer and a publisher and it's the way to make information available.

Eric Berlin: Are there any questions?

Andrew Kantor: We're going to go a little more on the WorldWide Web.

Eric Berlin: We did go over FTP and Gopher. Any questions on any of that? Nobody cares about that. They want the WorldWide Web.

Andrew Kantor: Nobody cares about FTP and Gopher, although they are very useful and there are cases when you want to use FTP or Gopher.

If you're a software company. But, as I said, you'll find all sorts of stuff — formatted text, graphics, photographs, sound and video, forms for user input. So I can have a Web page where I have a magazine and my poetry and I can have a little box on the bottom and I say, "enter your comments in the box and click the Send button." The Send button is part of my page and I can get input from users. I can have users type in things and I can search for them. I can take input. It makes the Web interactive. I can take input and act on it somehow. Maybe it's just, "send me a message," and you write your message here and click there. We're going to show you Web pages that do that, but just about anything you can imagine can be put on a Web page now.

If you're a store you can put a form that says, "enter your credit card number, enter your mailing address and we will send you whatever it is you want to order." This is why the Web is so important; and, as I said, you have links to other pages.

Corporations will put in information about themselves. Bowling, Ragu, Mecklermedia, General Motors — any corporation, any organization you could imagine probably has a Web page with all sorts of information about themselves. Whatever they want to tell you. Maybe you can order things. Maybe it's just chatter about themselves.

You'll find stores, shoe stores — well, heck, you want a particular kind of shoe, you don't necessarily have to come into a store near you. You can buy it from me. Mail-order catalogues have been around since the 1700s. Well, now, it's Web-order catalogues. It's the same thing. You can browse a catalog, you can order things. Stores are doing that.

And people collect information. Hey, I have the ability to put up a Web page because my Internet service provider says that for \$10 a month, you can put Web pages on our computer. So I can put anything I want. Well, maybe I'm a big *Star Trek* fan. I can put all sorts of information about *Star Trek* or *Babylon 5* or *Beverly Hills 90210* or whatever you want.

I want to collect information on a particular subject. Maybe I'm a big gardener — I can put gardening information up there. Maybe I just learned something new. Hey, I just found out how to rebuild a transmission, so I'll put on that information. It's my page, I can put whatever I want on it.

Lots and lots of people put information up there, and programmers do all sorts of neat things just to show off. You can find a Web page in Estonia that has an Estonian to English conversion dictionary. Type in a word in English and it converts to Estonian or vice versa. Some programmer puts that up there.

But all sorts of information is up there; and, of course, magazines and newspapers — *Time* magazine and *Time-Life* is up there. *Internet World* is up there. *The New York Times* is on

the Web, to an extent. *People* magazine. All these magazines are putting information on the Internet. How are they doing it? They're doing it on the WorldWide Web.

Eric Berlin: As well as people who are creating specific magazines for the Web. They didn't have published magazines. But they looked at the Web, and they said, "oh boy, here's an opportunity for us," and now there's a magazine called *Word* that is only available on the Web. *Living Digital* is a magazine being put out by Prodigy. They didn't have anything published beforehand and they are all offering all kinds of content and live chat, even with people. Yes?

M: [inaudible]

Andrew Kantor: Very good question. We'll get to it in one second. My magazine is on the Web. How can a magazine make money if you're putting stuff on the Web?

The reason people are making these on-line magazines — by the way, it's expensive to make a magazine, get it printed, get writers, make something large enough, get it on newsstands. I mean, there's a lot to deal with in trying to get a magazine published in paper form. But on the Web, if you create a good magazine, it's just a matter of doing a little coding, a little computer-eze.

The language is called HTML for Hypertext Markup Language. That's the language of the WorldWide Web. It's basically just plain text, typing things in. When we show you a page, we'll show you what the coding looks like. And you can create a magazine about whatever subject you want — all about yourself, if you think you're that important that people will come and see and read about yourself this week.

Now, magazines are putting content on-line. Well, how come people are saying, well, why should I subscribe to *Internet World*? I can get it on-line. Well, there are different reasons. One is, not everybody is on-line. There may be 30 million people around the world, but not everybody is. So magazines are really not worried about people cutting in or on-line versions cutting into their sales because not that many people are going to do it.

They are also not worried about it because you can take a magazine on the bus or the bathroom or stick it in your bag to maybe read in a hotel room. It's not that easy. People don't like reading from a screen. Your eyes start to water and they get all tired. People like a paper magazine. It feels really good.

Eric Berlin: Magazines are not putting all of their content on the Web. *Internet World*, for their present issue, I think they make our column available. I think they make a couple of news items available.

Andrew Kantor: You can't sell enough magazines with our column in it, so they have to put it on-line to let everybody read it.

Eric Berlin: Just a few things to whet your appetite to go out and buy the full thing.

Andrew Kantor: You'll find the table of contents.

Eric Berlin: It's basically advertising. Back issues are fully available, I believe.

Andrew Kantor: The way we work is, the current issue, you have a couple of articles; the one back, you have some more; one back, you have some more; and then like four issues back, you can get the full text and it's searchable. So that's what we do. That's our model.

Playboy does that. *Playboy* has the interview and a couple of articles and then a table of contents. So it's like, okay, I want to buy it. People actually go to the *Playboy* page to read the articles. So that's one way of doing it.

The other way is to say, "let's put the whole text up there and see if it really cuts into our sales." And people find it doesn't because it's like... they won't put all the pictures up there. They'll put some of them. And people like the feel of a magazine. Does that answer your question?

Of course, people put information about themselves because they can.

Eric Berlin: So, this is the way...

Andrew Kantor: It's true. There are personal Web pages up there by the thousands because people have egos and it's like, you know, I want to put information about myself up there; or if you give someone a business card and you look at a business card, okay, it's got my name and my company and my title, you know, got a little bit about me, but if I point you to my Web page I can say, "you want to find out more about me? Come to my Web page. I'll tell you what I do, what I cover, why I'm around."

Eric Berlin: A whole résumé is there.

Andrew Kantor: Yeah. People put résumés on-line. People put job listings on-line. A lot of companies will say, "jobs available."

Eric Berlin: This is how to advertise on the Internet. Posting to thousands of UseNet newsgroups is a sure way to hell. Here is the way to do it for real.

Andrew Kantor: A sure way to hell. Yes, we have checked with the Catholic Church and you will go to hell for advertising on UseNet news.

Eric Berlin: Furthermore, if you have an interesting Web page, this is where the gold rush is. If you have an interesting Web page, if some guy — some programmer stayed up one night and came up with a Web page which is actually a paint-by-number program. You can paint trees and homes and things like that, and he thought it was just a cute little thing to do, and suddenly all these people are coming to his Web page to try it because people like that kind of wacko thing.

Andrew Kantor: Or in some cases, to come back, maybe he puts information about a particular subject that he updates every single day and lots of people are coming to check that information.

Eric Berlin: He suddenly realizes he's got a little property on his hands.

Andrew Kantor: He's got a billboard by a highway that lots of people — I shouldn't have said highway. He's got a big billboard that people are driving by, people are coming to see this billboard that he has created.

Eric Berlin: People are now selling advertising on their Web sites. In a few minutes, we're going to show you *Yahoo*. *Yahoo* was created by a couple of college students who, once upon a time, when you were able to do something like this, collected every single page on the WorldWide Web. Don't even try it.

Andrew Kantor: David [Philo], by the way.

Eric Berlin: [They collected] every single page on the WorldWide Web and list them in categories and make a sort of index.

Andrew Kantor: They came up with a table of contents for a lot of the Web; not all of it, but a good chunk of the Web. Interesting pages, divided by categories.

Eric Berlin: Now the Web has exploded and there's no way to keep up with it, but it's still one of the most traveled sites on the WorldWide Web. So they're selling advertising. Very expensive advertising because people know that Net surfers go to the *Yahoo* page and they know the advertising is going to get seen.

Andrew Kantor: So two Stanford students who just... they weren't even that creative. All they did was create an index of stuff that was already out there and put it on their Web page just for the heck of it. They are now making millions of dollars in advertising because everyone knows — oh *Yahoo!* *Yahoo!* *Yahoo!* They're out there on the floor somewhere. So that's another reason people are putting stuff on the Web because if a lot of people are coming by, then why not sell ads?

Before I go to this, you may hear the term “hits.” Our Web page gets 10,000 hits a day. A hit is a misnomer. It's kind of a vague idea that someone has seen something on your page. If you have, like, five pieces of text on your page and someone views it, that's five hits. But hits is kind of like, right now, the only way people can talk about how popular the Web pages are. When I show you a page, I'll explain why hits doesn't really mean anything because some Web pages can get... just looking at one page can be 50 hits. Looking at another page might be one hit.

Eric Berlin: This is one of those things — how popular are Web pages is one of the things [where] we are on the cutting edge of technology. What we're saying here might be different in two weeks because people are, companies are coming out with rating systems. Even Nielsen is getting involved in this. Rating systems to find out precisely how popular things are, so the term “hit” is going to become antiquated soon enough as the technology gets more specific.

Andrew Kantor: So what you might see that tells you every page on the Web has an address. It all begins with `http://`. Every page on the Web begins with `http://`. It stands for Hypertext Transport Protocol. So, `http://www.bigcorp.com`. That's our Web page or our Home Page. A Home Page is considered the first page you see. So Ragu has five pages on the Web — the first one you come to is their Home Page.

Another one may say, we're on the Web at... and they'll give you a specific `http://www.somewhere.com/info/home.html`. They may give you a specific address. This tells you to go to a particular computer, particular directory, particular file. This one is saying, just come to this computer, and it's automatic, you're going to see the file we want you to see.

Eric Berlin: I'm going to take this off...

Andrew Kantor: What we're going to do...

Eric Berlin: This computer here is connected by a dial-up connection. It's on a 28.8 modem, which is fast as modems go, but way slower than a network connection, which is what this computer has. So I'm going to jump over here and try not to electrocute myself.

Andrew Kantor: Or me. We were talking about whether we should demonstrate the Web. This is how you would see the Web with a 28.8 modem, but then you're going to get very frustrated because it is pretty slow, especially when there are pictures. Let's focus this.

Eric Berlin: Where shall we go?

Andrew Kantor: Let's go to *Yahoo*. If you look at the top, this is a WorldWide Web browser. This is a piece of software that will allow you to view the WorldWide Web.

Eric Berlin: It's called *Netscape*.

Andrew Kantor: You may have heard of it.

Eric Berlin: It's taking over the country.

Andrew Kantor: It's the successor to *Mosaic*. The people who designed *Mosaic* while at school, left school, joined *Netscape Communications Corporation* and created *Netscape*.

A guy named [Mark Andreson]. He was the main programmer at the National Center for Supercomputing Applications in Illinois. He designed *Mosaic*. He came over to *Netscape*, where he now makes \$58 million dollars — he's a 24-, 25-year-old programmer. So people are making money on the Internet.

Let me show you, as fuzzy as it is, what this looks like. Okay. This is *Netscape*, and let's start with *Yahoo*. This is the *Yahoo* list that we were talking about. Now, if you look at this page, there's not a lot on it. There's this nice fancy graphic that says *Yahoo*, and you can't see it very well, but there are buttons you can click on up here with new cool popular headlines. Anything in blue is something you can click on.

Yahoo has a table of contents, so by definition you can click on just about anything. And there's also a box where I can search for something. So if I were to click on a button that says Arts, it brings me to another list, another page of *Yahoo*. Arts. Subcategory listing: Indices, Architecture, Art History, Body Art, Ceramics, Children. This is the *Yahoo* page, and I can click on literature: awards, beat generation, books, children. *Yahoo* is an index of the WorldWide Web.

Let me show a general page. This is why I always start with mine. This is my page on the Web. Very simple. Hello and welcome to my Web page. This is as basic as we can get because I don't have time to do more. Hello and welcome to my Web page. I've put a little text in here. You can't see it, but you can click on Eric's name. You can click on some things. If you scroll down, I put a picture up there. If you scroll down, there's some personal stuff. Who I am, what I've done. I just put this information about myself because people are always asking for information about me, so I said, come to my Web page and I put links to Eric. I put links to other pages. I created this Web page.

Go to Ragu.

Eric Berlin: Ragu.

Andrew Kantor: *Netscape* is unable to locate the server.

Eric Berlin: Are you sure it's www.ragu.com?

Andrew Kantor: Yeah. Okay. This is the Ragu Home Page. Ragu, the company. Mama Cucina, brought to you by your fellow Netheads at Ragu. Well, I haven't seen anyone as hungry-looking as you since my great Aunt Lucilla ran around chasing a chicken with a fork.

Scroll down a bit. They put a picture up.

Mama's new sauces. Mama's Italian cookbook. You can click on any of these things. The people at Ragu have done this. Why? Well, out of the goodness of their hearts and for no other reason, they're putting this information on the Internet, specifically on the WorldWide Web so you will come and look at it and that's all they want.

Oh, by the way, the word Ragu is going to be all over the place. Every time you see it they're advertising their own product. Look, new recipes, new sauces.

Eric Berlin: Learn Italian — that's a good idea.

Andrew Kantor: Is there a question? You, the troublemaker?

W: [inaudible]

Andrew Kantor: *Netscape* is only a piece of software. It does not contain any information of its own. *Netscape* lets you view pages on the WorldWide Web, that's all it does. And *Netscape* has some buttons on it, which we don't have up here, like, let's say, search. What that does is it just connects you to a page on the Web that the people at *Netscape* knew about that lets you search. That's all it does — all *Netscape* does is let you view pages on the Web. They have put some of those pages automatically, if you click search, it bring you to a search page.

M: [inaudible]

Eric Berlin: There are search engines out there, and if you go to them often enough, which you will, you can set up bookmarks for them and just learn how to type in www.yahoo.dot.com, just click on the right button, and you will be right over there.

W: [inaudible]

Eric Berlin: Oh yeah, you will get what you're looking for, and then some. If you search on a particularly... if you search on a common word, you'll find — somewhere in the midst of the information you'll get back — you'll find precisely what you're looking for, but it might be varied in 1,500 different pages about the same subject. When we do some searches we will demonstrate this very nicely.

Andrew Kantor Lots of people have said, "oh, the Web is so big, there are so many pages, and so much information out there, we are going to create search tools." *Yahoo* said, "we are going to create a table of contents, where you click up arts, and then click on something else, and you can make your way to something."

All the people — and then *Yahoo* kind of took this idea also — have created search engines. The best one out there is from a company called Open Text. Type in a word and it keeps track of as many Web pages as it can, as it physically can, which is thousands and thousands of them; and you type in a search sum, and it will tell you, "these following Web

pages contain the term you want.” So if you type in the word “Bill,” you’re going to find thousands of pages; if you type in “Bill Clinton,” you’ll find a few hundred pages; if you type in “President Bill Clinton,” maybe you’ll find even fewer.

Eric Berlin: We’re going to be showing how to search on the WorldWide Web, and how to use the Internet as a whole in the just a short bit. Does anybody have any questions about what you can accomplish on the WorldWide Web? What it’s for? How you link the things?

Andrew Kantor: Pages can contain anything. This page contains mostly pictures that you can click on. Click on something, click on Mama’s Italian Cookbook. Now, they are linking to pages — as I said, you can create a link to any other page on the Web — they are linking to their own pages, which kind of makes sense. You don’t have to link to outside pages, you can link to your own pages. So let’s see.

Eric Berlin: Lot’s of them, all of which will include Ragu spaghetti sauce, I am certain. Seafood.

Andrew Kantor: Whoa, so the people of Ragu have taken the time to put in the Web server all this kind of stuff. Pick another page. That White House stuffed...

Eric Berlin: You want me to write down this recipe real quick or not?

Andrew Kantor: Oh, oh, oh. Now there is one jar, 14.5 ounces, of Ragu Alfredo Classic pasta sauce; notice that title, as you can click on it, so you get the recipe. And, of course, they mention Ragu. You go there, and... oh, look, there is a picture of the label, and this is how Ragu gets you. So what they are doing is they have a billboard, they give you information, and they are counting on you to be, to hear Ragu, Ragu, Ragu, over and over again. I bet after this seminar, you are going to be in the store and you’re going to be thinking, I want Ragu. Now, questions over there?

M: [inaudible]

Andrew Kantor: Netscape is just software. I hope they don’t hear me on the show floor. Netscape is just a piece of software. It’s a very good piece of software — except for the newer version, which has some quirks — but it is just a piece of software. You have e-mail programs to send e-mail, you have Netscape to view pages on the Web.

This is the White House page. The White House, out of the goodness of their hearts and using your tax dollars, has created a page of information. An interactive citizen’s handbook. President’s Welcome Message, Vice-President’s Welcome Message, Tours, The First Family.

(Now I don’t think we have a sound player hooked up.)

Eric Berlin I don’t think we do.

Andrew Kantor: If we were to click on one of these, we could listen to President Clinton welcome us. We are not going to do this, but we could.

Eric Berlin: You can see the President’s welcome message in three formats.

Andrew Kantor: Test format.

Eric Berlin: I was very concerned for a moment.

Andrew Kantor: So this is what the White House has done. You can find congressional bills, also just stuff that...anything you can imagine is out there, because someone cares about it and someone has taken the time to do it. Paramount Pictures has *Star Trek* information, for example; lots of information about the series, products you can buy and all sorts of things like that. But I tell you, there is more information put out there by Trekkies who created their own pages with information that you may not know, information that Paramount may not feel like publicizing, or things that they care about. So people put lots of information.

Eric Berlin: Movie companies are taking domain names for movie titles, so you don't have to know Paramount put out such and such a film. Nowadays, you can just go to www.strangedays.com and you can go download a picture of whoever is in that movie.

Andrew Kantor: Jimmy Buffet was on the radio the other day. He was talking about things, and he said, "You know, people on the Internet know more about me than I do." And it's kind of true. I mean, you forget things about yourself, but people, if they care about you on the Internet, they are going to write lots about you.

Eric Berlin: That's an example of... strangedays.com probably isn't going to exist next year, but it's a good PR move for the time being.

Andrew Kantor: Get information about the movie — it's a teaser. Oh, I'm really into this movie. I want to see a picture. So, whatever you can imagine, people are putting it there. You can put pages on the Web. You own a company — you're a big company, you're small company. If you're a big company, you probably have computers connected to the Internet directly and you can put stuff on your computer. If you're a small company you go to your Internet access provider, and say, "hey, what do you charge me to put up a Web page?"

PANIX in New York charges \$10 a month, or whatever they charge, they charge a few dollars a month, and they will host your Web page. I call them up and say, "I want to do this" They mail me \$10 and they say, "okay, here is the directory." Anything I put in that directory is on the WorldWide Web. So I have to code the files.

Go back to my page, let me show the coding. That's Internet World's site iWORLD, which you will see out on the show a lot. I am supposed to talk it up — you know, it's a nice site, there is lot of information.

Okay, here is my page. I need to type all this in and say, make this big, make this small, make this a link. If you go into *Netscape* and view by document source, you will see this is what I had to type: Title: Andrew Kantor's Page; H3 up there, that's the H e-mail code; make this fairly large. Hello, welcome to my Web page.

Eric Berlin: There is the picture.

Andrew Kantor: Yeah, and I know the code, I have to type this in, put in a folder, which I have scanned and uploaded. I tell them how big to make the folder. I'm not a programmer at all. I didn't use a special tool to create this. I used basically *Note Pad* and two fingers, and I typed all this in. There is lots of software, lots and lots of software out there now to help you create Web pages.

Oh, just take this picture, drag it on, you design it, like right on the page, like desktop publishing, if you've done that, and then it converts it to HTML for you. I was old-fashioned and

somewhat lazy and didn't feel like loading up the software, so I did it that way. But you can create Web pages very, very easily right now. You can't create the fanciest pages in the world yet, but you can do a pretty good job. Okay, get this off the screen, please.

Eric Berlin Dialing up on to the Internet, this one, let's...

Andrew Kantor: Go back to *Yahoo*, or something, click on halt. Just get it off.

M: [inaudible] one page off of *Word* in your magazine?

Andrew Kantor: We are going to, we haven't yet. Later this year, in 1996, issues we will be looking at [will include] creation tools; we're going to be looking at the servers that companies use to put this stuff up. So yeah, we're going to be looking at that also.

There is a lot of freeware out there to help you create Web pages. There is a product called *Microsoft Internet Assistant for Word for Windows* that converts *Word for Windows* documents into HTML. It doesn't do a lot — it can put pictures in certain places, and it can do large and small text, and that's about it. But it is a really basic way of getting the coding down.

There are lots of books out there, tons of books on HTML coding. You don't need a big book, it's fairly simple. Coding in HTML and creating these pages — the more time you want to spend on it, the better you can make your pages. But for basics... I mean, my page took me half an hour to put up. It's really simple. If you read it, it says basically, "the only reason this is here is that people ask about me and you can all go to hell." Because some people put lots of links and junk in their page. I'm not like that.

M: [inaudible]

Andrew Kantor The question is, is there any better way to access this? I've got *Netscape*, I've got *Trumpet Winsoft*, *Trumpet Winsoft* is a freeware program for Windows that lets you dial-up an Internet access provider. You buy Internet in a box, it comes with a dialer, it's really easy to configure. The trouble... *Winsoft* is quite as easy, but it's free. [Inaudible] has that connection to the Net, and then you launch *Netscape*. What don't you like about it?

W: [inaudible]

Andrew Kantor: It doesn't work? What, it crashes a lot?

W: [inaudible]

Andrew Kantor: You have a dial-up connection.

W: [inaudible]

Andrew Kantor: Okay, the problems that your having — that it's dialing and stuff like that — that is a *Trumpet Winsoft* problem. You get what you pay for — *Trumpet Winsoft* is old and it's free. So it's not very good. I would suggest getting *Internet in a Box*, or *Chameleon*, or any of the other products. *Internet Suite*, *Emissary* — any of the other products that are out there instead of *Trumpet Winsoft*.

M: [inaudible]

Eric Berlin: Your problem is not with *Netscape*, your problem is with your dialer.

M: [inaudible]

Andrew Kantor: Yes, I should clear that up. We mentioned in here that when you connect to the Internet you're doing two things. One, you are dialing your provider, dialing their phone number with your modem, and making a connection. Once you have made that connection — ERRRR... you know how it sounds — you are now on the Internet. You can use any Internet tool: you can use the e-mail program that comes with *Emissary*; you can use the mail program that you downloaded from the Net Eudora; you can use *Mosaic*, which comes with *Internet in the Box*; or you can use *Netscape*. Any Internet program, they are called TCP/IP programs. Once you are connected to the Net, you can run any of these.

Eric Berlin: As we said in the first half, you can mix and match the applications to your heart's content, once you're connected to the Internet.

Andrew Kantor: So you have a dialer, and you have applications. Now these suites that you buy come with a dialer and 10 applications. Or you can assemble them yourself. You can get the *Trumpet Winsoft* freeware and you can configure that as your dialer, and then get these different applications, which is what a lot of people do, because the individual applications are better.

I use *Internet in the Box*; I use the dialer only. I use *Eudora* for e-mail; I use *Netscape* for the WorldWide Web; I use *Agent*. I just don't use any of their software except for their dialer. That's how I feel. That's what's better about the Internet than an on-line service — I have a choice of all this software I can use.

Eric Berlin: Now, using the Internet as a whole integrated thing. Basically, it comes down to if you have a question that you want to have answered, if there is information that you want to find, follow the same path each and every time. The WorldWide Web is best with general information.

Since general information is a good place to start, start with the WorldWide Web. Go to the search engines, as we will give an example in just a minute. Go to the search engines. And there are several different types of search engines. *Yahoo* arranges things in menus and allows you to search a little bit through those. *Open Text* will allow you to search for a phrase, as opposed to another search engine called *WebCrawler*, which will let you search for a few different kinds of words, though not necessarily in that order. For this reason, we like *Open Text* a lot.

Andrew Kantor: We will show you *Open Text* in a second. Basically, when you're looking for information of any sort on the Internet... For example, I need to know — my dad had prostate cancer, I got to find out about prostate cancer, what do I do? I want to buy a pair of rollerblades, what do I do?

Whatever information you want, there is a very distinct pattern of how to search the Internet for it. It is very simple: you search the Web, you look on the UseNet, and then maybe you send the e-mail. It's the same thing over and over again, and it works very, very well. Once you get the hang of it, it's very easy.

Eric Berlin: If you want to have a conversation with somebody, or get some questions answered that you weren't able to find on the Web, now you want to get more specific, go to UseNet news, see if there is a newsgroup about the subject that you're interested in.

Andrew Kantor: Gardening. Rollerblades. Transmissions.

Eric Berlin: The very first thing that you want to do is find what was called the FAQ file. This stands for "frequently asked questions." It is considered etiquette, or netiquette, before you post a question to a newsgroup that you have never been in before, to see whether that question has been asked and answered a hundred times.

Andrew Kantor: Let's say I want to find out James T. Kirk's middle name. I can go to a *Star Trek* newsgroup and post: "Hi, anyone know James T. Kirk's — what the 'T' stands for?" But if I'm smart and polite, what I do is I look for a FAQ file — a list of frequently asked questions. I read through it, and I say, oh, there it is — what is James T. Kirk's middle name. Someone has already asked that. People create these files because the same questions come up over and over and over again.

Eric Berlin: On most of the popular newsgroups somebody who contributes to that newsgroup a lot takes time out of their own day to arrange frequently asked questions into a file, which they post to that newsgroup periodically and also most likely make available on the WorldWide Web. If your question is still not answered, then, by all means, post a question. I guarantee you will have an answer in 24 to 48 hours, tops. Yes, a question in the back.

W: [inaudible]

Eric Berlin: We will show you that in a second.

W: [inaudible]

Andrew Kantor: The *WebCrawler* and *Lycos*.... we're going to talk about finding newsgroups. We are going to talk about the *WebCrawler*, *Lycos*, *Open Text*, and the search engines and how they work because they all work basically the same way.

Lastly, there is electronic mail. When you post to a newsgroup or you look on a Web page and you get information you want, most likely you will find the e-mail address of people who can help you. Maybe you will post a message to UseNet news asking a question, someone will answer it, and then you will have their e-mail address. Then you take it "off-line" rather than in a public newsgroup; you can exchange e-mail because you have got an expert. Maybe you will be on a Web page and you will see a note saying, "An expert on knitting wool is John Smith, jsmithcorp.com." Oh, well, I'll drop him a note and see if maybe he can help me. Of course, you are polite about it — it's like calling a stranger on the phone.

Eric Berlin: I was just going to say... I mean, it's a stranger, so you've got to be...

Andrew Kantor: A lot of people don't want to do that and you'd rather post publicly, which is fine.

Eric Berlin: That is basically what it comes down to, as far as information goes. Let's give a specific example. I want to buy a pair of rollerblades. I don't know the first thing about rollerblades.

Andrew Kantor: But it looks like fun and dangerous, and it annoys my mother, so I want to buy a pair of rollerblades. This is a true story.

Eric Berlin: I am wondering if there are mail-order places on the Web. I'm thinking there must be, but I don't know where they are. I don't know what brand to get. I don't know how much I should expect to spend. I don't know what kind of safety equipment I'll need.

Andrew Kantor: I want to buy a pair of rollerblades, what should do? Before I spend my \$200, do I have to spend \$200? What do I do? So [we turn to] what we said — Web, UseNet, e-mail — in that order. Web and UseNet should be all you need. First thing you do is go onto the Web and search for it. Let us show you. We want rollerblade information.

Eric Berlin: Are we still connected?

Andrew Kantor: Why don't you use the other computer?

Eric Berlin: I certainly will, but I don't know why this keeps knocking me out.

Andrew Kantor: The middle button again? Switch computers.

Eric Berlin: Switching computers...

Andrew Kantor: This isn't supposed to be like this. Any questions in general about this?

M: [inaudible]

Andrew Kantor: I am searching pages on the WorldWide Web; I am using one of these search centers. What do you need?

M: [inaudible]

Andrew Kantor: Yes, the search engines search more than just Home Pages. They search — the good ones search every page on the Web.

M: [inaudible]

Andrew Kantor: Right. With all this stuff, I'm not using my CPU power at all. *Open Text* is a site, a company called Open Text, their site contains a search engine. So what we are doing, we are going to get to *Open Text*. How do you know about *Open Text* — well, you're learning it now. So you should write these addresses: www.opentext.com

Eric Berlin: This is the home of the *Open Text* index. That's precisely what I want. I click on the link and I'm brought right to it.

Andrew Kantor: Simple search.

Eric Berlin: They have a simple search, but they also have a power search where you can search for this term but not that term, or this term, but make sure that this term is mentioned a lot; and this other term only a little. That's a "wadded" search.

M: [inaudible]

Andrew Kantor: You can do Boolean searches. You can do incredibly complex searches. If you go to the top, you notice Video Online has advertised with *Open Text*. *Open Text* has got a great search engine. Lots of people come here, and every time you come to *Open Text*, you can see this little Video Online thing. By the way, if you click on that it brings you to Video Online's page. So it's like interactive advertising. Like our billboard here; if you're looking at one billboard, maybe you can see another billboard instead.

But right now we are interested in searching, so we are going to go back one page, to the general *Open Text* search engine, and we are going to type in rollerblades, also known as in-line skates. We will see what it comes up with. Please work. Ninety pages containing the word rollerblades.

Eric Berlin: Now, *Open Text* puts things in order, it has a scoring system, as you can see here. Let me scroll it up a little bit. A scoring system. This page has the word rollerblade a lot, and so they put it number one. It doesn't [inaudible] what I want, however.

Andrew Kantor: Rollerblade of the Silver Mist.

Eric Berlin: It looks like a work of fiction by John A... Okay, this is not what I want. So...

Andrew Kantor: Summer plans, for the rest, give me a call and join in. Sorry, I can't give you... This looks like somebody, somewhere, is making summer plans and is telling the entire world what their summer plans are. Like I said...

[Tape change]

Andrew Kantor: [This page comes from a] senior in computer science at the University of Illinois. Showing a little bit of the page: "I have many interests, which range from rollerblades to legos." She is a senior in college — what has the education system come to?

Eric Berlin: Hey, look what we have here.

Andrew Kantor: Oh, nice gig. Skate Merchants; New York City in-line skating guide. Skate Merchants.

Eric Berlin: We click on that, that sounds most promising indeed.

Andrew Kantor: New York City In-Line Skating Guide. Oh, so it lists places in New York City that you buy rollerblades, by borough — Manhattan, Brooklyn, Queens, Staten Island. So let's see...oh, and mail order. Mail order.

Eric Berlin: Mail order. Here we have a mail order rollerblade company. Team Paradise. They are in California — not that it matters, because it's mail order.

Andrew Kantor: Now, what just happened? To put it in perspective, we went to *Open Text*, wherever that is. *Open Text* pointed us — we searched on rollerblades — to a page on a computer in New York run by PANIX, which I guess Eric knew about. So we came to that one by PANIX.

Eric Berlin: Oh, no, I really didn't know.

Andrew Kantor: Someone at the New York City Skating Society or whatever put this information up, and it's housed on PANIX, and part of the information they put is a mail-order company that sells rollerblades. So by searching, we ended up from *Open Text* to this page and possibly we can connect to Team Paradise, if we click there.

Eric Berlin: This is a link that will allow us to send e-mail.

Andrew Kantor: We haven't set up...

Eric Berlin: Had we set it up correctly, which we didn't, we could click on this and send e-mail to them and ask for information about their mail-order catalogues.

Andrew Kantor: Send me your catalogue, blah blah blah... Go back to the search on rollerblades. See, when you search on something, you come up with lots and lots of information. I mean, it's easy to use the Internet to search for things, but once you find them, of course, you are finding a lot, a lot of things.

Eric Berlin: Number nine. Here we have a Gopher menu, which we can view with the WorldWide Web browser. Gopher has been folded into the WorldWide Web in this way.

Andrew Kantor: Here we have number ten. Pictures of Tom doing really deadly and sick stunts that haven't been taken yet. Keep going. Anything else?

Eric Berlin: Well, yes, we have more. I mean, I think we got the gist of it here.

Eric Berlin: But I still don't — surfing is the art of getting distracted. Suddenly we are talking about Tom's sick stunts, like I care. I still don't know how much money I should expect to spend. I don't know what kind of safety equipment I want. I think that there is a newsgroup about rollerblading and I hope that they have a FAQ file. I am going to try to find it on the Web. So I am going to search for, not this phrase, but all of these words. I am going to search for a document that has both rollerblades, and FAQ file, and hope that I wind up with the rollerblades FAQ file.

Andrew Kantor: The other thing, of course, is rollerblades is one brand. What we should have searched on, now that we think about it, is in-line skates. In-line with a hyphen, in-line without a hyphen — and that probably would have come up with more pages. So a good deal of that is thinking, what should I search for? And being as specific as possible.

See, we are searching on rollerblades FAQ. Is it coming through? Try that again, try hitting enter, clicking on the box and hitting enter instead. (All the comments I'm making are ending up on the tape and the CD of the show that you can buy, which is kind funny, you can listen to this and have no idea what we're talking about.)

Eric Berlin: There we go — 14 pages containing rollerblades and FAQ.

Andrew Kantor: RSS In-Line FAQ. Now RSS In-line, just from my experience, is probably a newsgroup. The R is probably for .rec, I don't know what the others would be.

Eric Berlin: REC is for skating in line.

Andrew Kantor: The only things that really have FAQ files, or the main things that have FAQ files, are newsgroups, so these two links both point to the RSS In-line. I bet it's REC Sports Skating In-line — RSS In-line FAQ files ports. Now we searched for the word rollerblades, and since this is actually about in-line stuff, it pointed us to the sections that have...

Eric Berlin: Here is the part about where to skate in North America; here is the marketplace, the guide to buying in-line skates. How perfect is that? We click on it.

Andrew Kantor: We could also have used our UseNet newsreader to go to this newsgroup. To search the list of newsgroups that we have, that our provider gives us, search for the word rollerblades, search for the word in-line skates, and come up with a newsgroup, then go to the newsgroup and see if the FAQ file was posted there. But in this case it's also on the Web, and we happen to be on the Web, so we will search it. It's a little faster.

Eric Berlin: That first attempt didn't work; and if for some reason it didn't work, we have backup resources. The FAQ file is posted periodically to the newsgroup as Drew just said. What is this guide? This guide is not review-oriented — see 3.3 for the FAQs for skate reviews. So I can jump over there if I want specifics on that.

Andrew Kantor: Warning: This guide may be offensive to salespeople who pretend they know something about skates when they sell them in stores. Tough nuggies.

Eric Berlin: Here is a checklist for you to print out to take to the store. Whoa.

Andrew Kantor: Now the reason I picked rollerblades is this is exactly what I went through when I was going to buy rollerblades. I thought this was a cool experiment to see if I could use the Internet to buy rollerblades, and it worked out very, very well. So I went through just about everything you are seeing now.

Eric Berlin: Just like Tony [Chen] went through the trouble of making a form for you to fill out for yourself. What type of skating will I want to do? Multipurpose, hockey, speed. Well, multipurpose. What is most important to me? Price, fit, and comfort. He actually has fit and comfort for you. Evidently leaning you in that direction. Deciding on your price range — the crummy skate threshold.

Andrew Kantor: \$130 to \$190.

Eric Berlin: Yeah, middle range.

Andrew Kantor: You also need safety gears.

Eric Berlin: The whole nine yards.

Andrew Kantor: You don't need elbow pads. So this is a case of searching on the Web and you actually find some really good information that someone put up there about getting rollerblades.

Eric Berlin: He goes on and on and on. Very impressive.

Andrew Kantor: Okay, and also a table of contents, other FAQs. Stopping. Well, you can figure out what stopping means, it is probably an important thing to read. Grinding and Vert Jumps, I'm not sure; Slalom, makes sense; Figure Skating, Racing, Buying Guide so you can go... He has put all this information on his Web page. Yes, ma'am.

W: [inaudible]

Andrew Kantor: We are going to do that next.

Eric Berlin: We are going to do that right now.

Andrew Kantor: What we are doing first, as we said, is that we are going from the general to the specific. What we are trying now is to get general information about a subject. In this case rollerblades or in-line skating. We are going to get to the specifics in a second. Right now I want to buy rollerblades, I don't know much about it.

M: [inaudible]

Andrew Kantor: Theoretically correct. I could have gotten to the same place using *Yahoo*. I probably could through *Yahoo*, through sports and recreation, and then skating, and then in-line skating. I could have made my way through *Yahoo* and ended up in the same place. That's very possible. I could use another search engine and ended up in the same place. There are lots of different ways; lots of different places point there. Like I said, we are going from the general to the specific, this is the general, this is I want information about a particular subject — in this case, rollerblades.

Eric Berlin: *Yahoo* has a recreation, there is sports...

Andrew Kantor: If you have only two links — what is called your hot list or your bookmark file — have *Yahoo* and *Open Text*. But not in that order — have *Open Text* then *Yahoo*. *Open Text* is www.opentext.com or rather <http://www.opentext.com>. *Yahoo* is — anyone? — www.yahoo.com.

Eric Berlin: Skating: 94 links.

Andrew Kantor: I'll switch computers here; again, I'm back on my fast computer.

Eric Berlin: In-line skating: 47 different links. Now *Yahoo* does not put every single page that deals with rollerblading out there. So we may not have Amy's little side of the Internet in rollerblading because *Yahoo* just doesn't deem it important enough.

Andrew Kantor: We do have the aggressive in-line skating in Finnish and in English.

Eric Berlin: We don't have Amy — we do have Christine's corner. So after you've done your basic research, you can come back here and pretty well finish up, or fill up your day reading about rollerblading. And if after all that, you still have questions... I'm going to go over to the news.

Andrew Kantor: Okay, then let me explain what actually...again, this is a true story. I got this information, I read through the file you saw and I went out and I was about to buy a pair of rollerblades — what do they call it, Bravo Blades. *Bravo Blade GL*. I'm like, okay, well, this seems to fit everything I have read in the FAQ file, about what to look for in a skate, the price is good, blah, blah, blah, but I don't know about this particular brand. I need specific information that is not in the FAQ file.

We go from the general to the specific. I used UseNet news to get the specific information. I found the newsgroup, I go through the list, and I search on... well, Eric searched on in-line or skating? What did you search on?

Eric Berlin: Skating.

Andrew Kantor: Searched on skating. We have a bunch of rec-sport skating. Ice Figure, Ice Recreational, In-Line, Misc, Racing, Roller. Roller may have been a good one also. But rec-sport skating in-line. I would go to that newsgroup and I would read the messages. You're going to do that now?

Eric Berlin: It's coming in now.

Andrew Kantor: Readers' recent messages. See if anyone mentions Bravo blades, because that's what I was interested in.

Eric Berlin: Let's see if this is actually going to happen - a little *deja vu* occurring here.

Andrew Kantor: Wow. Now, like we said, the FAQ file is often posted to the group, so here it is.

Eric Berlin: [inaudible] it's multi-part.

Andrew Kantor: Stopping, Skidding, Backwards, Stairs, Grinds and Rails. Vert and Jump Slaw, Figure Skating, Racing, Guide To Buying In-Line Skates, which we saw on the Web also. Skate Reviews. I could tell you, I went to skate reviews, the Bravo blades were not reviewed. People have to send in reviews.

Eric Berlin: But nonetheless, that could be a heck of a [inaudible].

Andrew Kantor: That's what I would do. I'm interested in Bravo blades. Okay, I want to buy Bravo blades. First thing — skate reviews. I would go to the skate review thing and see if the specific information I wanted was in there. Why don't you open that?

Eric Berlin: Which heading is that?

Andrew Kantor: Skate reviews. Right there. Okay, it's going to...

Eric Berlin: I'm on the 28.8 modem and it's not just beeping up anymore — it takes a little bit of time. This is more like how your experience is going to be unless you have a lot of money and something to...

Andrew Kantor: So I would look there. I would go through that and I would use the find command and search for the word Bravo. If I saw it and then someone said Bravo blades are wonderful, or the GL is good, but the GLX is not or something like that, I would take that into account. If not, I would post a message to the group, and I'd say...

Eric Berlin: This is a very big file we just tried to upload.

Andrew Kantor: Do you want to stop it?

Eric Berlin: Especially since we know Bravo isn't there, yeah. So I'm going to stop this task.

Andrew Kantor: No, no. Okay, skate reviews, so I would use the find command — different news reviews have different find commands. The [Ejan] has one. Find what? I would search on Bravo. Maybe there is a review there now. This is a review of Aeroblades or something.

Eric Berlin: Aeros.

Andrew Kantor: I understand that Bravo blades are a bit wider. Well, that doesn't tell me much. Rollerblade, Bravo Blade Junior. Well, I'm not interested in smaller skates. Search on it again — here is review of Bravo Blade Junior, the boot, the closure, blah, blah, blah.

Eric Berlin: That was the last one.

Andrew Kantor: Unable to find Bravo. I mean, you get the basic idea. You don't have to go through incredible detail. Okay, that's the information I don't want there; the information I want is not there.

Eric Berlin: Let's see if anybody is talking about it on the newsgroup itself.

Andrew Kantor: I'll search and see if anyone has created a subject header with Bravo in it. Nothing in there. Okay, so no one has asked that — it is not in the FAQ file. I'm not going to offend people by asking a question that's going to be asked a million times.

So I post a message, and I say: Bravo Blade GL, any good? That will be my subject. I post a message to the group and I say I want to buy them, they look pretty good, this is the price, are these decent skates. I post and I wait a couple of days — maybe it's later that day — and people will write back, as they have, and people say, they're very good, except for this, and watch for that and make sure you don't do that. People give me the specific information I want.

So you start with the Web for the general information on this particular subject area, then once you got what you want, you look on the UseNet to see if people are discussing the particular thing you want to know, the particular brand of skates, the particular medical condition you have, the particular bicycle, or particular anything you want to name.

Eric Berlin: Somebody could jump in over the e-mail for a second; if somebody on there, for instance, has Bravo Blades, but you have heard complaints about them, you can send that person e-mail, saying, "But haven't you experienced such and such?" Thus you take the conversation, as you said, "off-line" and now you're using e-mail to further your quest for the blades.

Andrew Kantor: If someone wrote to me, as someone did actually, and said, Bravo Blades suck; and I said, can you tell me exactly how they suck? And he said this buckle doesn't work, and this end had this problem. Someone else wrote to me, and I said, "well, someone told me they suck," and I got into conversations with two people via e-mail about what was good and what was bad about them. I ended up buying them.

Eric Berlin: So now that we have beat this topic to death, let us actually break.

Andrew Kantor: Five minutes leave for our coffee break.

Eric Berlin: While you're out there, think of those things that you want to find yourself. Not just information you want to find, but things that you want to accomplish with the Internet. It doesn't have to be going and buying a product — as a matter of fact, we prefer it not being that.

Andrew Kantor: We've done the buying a product thing. Think of questions you have, tasks you want to do. I mean, this was planned — we searched on this before and we made sure that things would work. Give us something and challenge us, and maybe we will be able to find information. You'd be surprised what is actually out there on the Net.

Eric Berlin: We will also be covering little tips and tricks on how to find the right mail list that you're looking for and other such things. So go and have cup of coffee and come back with lots of challenging things.

[Break]

Andrew Kantor: Everybody back? Is anybody not here? We just had a question: What is the difference between a Web site and a Home Page? A Web site, an organization's Web site is going to contain possibly several pages.

In Yahoo's case there are dozens and dozens of pages, but a site can contain several pages. The first page you come to — Ragu, we went to www.ragu.com — that first page is considered the Home Page. Then there are other pages underneath it on Ragu's Web site. So I talk about what's on my magazine's Web site; it could be on the Home Page, or it could be somewhere in there. It's kind like the Web site is the neighborhood and then we talk through individual buildings.

W: [inaudible]

Andrew Kantor: If you wanted to package a basic set of tools, of Internet tools, I only use Windows — unfortunately, for you. But for Windows, I would get *Internet in a Box* because I think they have the best dialer around. *Chameleon* comes free with a lot of things. I hate *Chameleon's* dialer, although *Chameleon* is a powerful package. I would get *Internet in a Box's* dialer.

For e-mail, I would use *Eudora*, which is available from a company called Qualcomm. They are here somewhere at the show.

For UseNet news, I would use Forte's agent — a freeware version called *Free Agent* is available. I don't think Forte is here. But Forte's agent. I don't know if you could buy that in the stores either. I know you can contact them at www.forteinc.com for the UseNet newsreader.

For the WorldWide Web, there is no contest. *Netscape* is the only way to go. *Netscape* can do things the others can't. *Netscape* is free on the Web at www.netscape.com — you can download it. Also, *Netscape* is here and you can buy a registered version of their browser.

What else is there? That's basically it. You don't need a separate FTP application — although you can get that — because *Netscape* does FTP, *Netscape* does Gopher.

So I would say *Eudora*, *Agent*, and *Netscape*. Plus a dialer, and *Internet in the Box* is the best dialer. If you have a direct connection from your office and you don't need a dialer like I do, then just get those three products. There are freeware versions of all of them or you can pay a little money and get the commercial version. They're just absolutely terrific.

M: What was the dialer [inaudible]?

Andrew Kantor: The dialer actually dials your Internet provider, dials your modem and connects you to the provider and negotiates. It says, "Hi. I'm establishing an Internet connection — okay, you're ready, I'm ready" and it connects you and then lets you use all the applications.

Eric Berlin: This is my dialer. It's when I click on my dialer...

Andrew Kantor: Can you clear the screen because it looks — go to view.

Eric Berlin: Clear the screen?

Andrew Kantor: Edit, try edit. Clear window. Okay. This is his dialer.

Eric Berlin: And what will happen when I connect... Well, that didn't work.

Andrew Kantor: Yet you listened to me when I gave you those instructions. This is the dialer that comes with *Internet in a Box*, and you can set up different configurations. If you're calling from different places, if you have different phone numbers, all you have to do... basically, the only buttons you need to worry about are dial and hang up.

CompuServe will give you this, a version of this for free, which will only work with CompuServe's connection — but CompuServe isn't a bad Internet provider — and it only has dial and hang up. It lets you configure things in other places. Can you go to network, can you show that configuration? We're on-line, aren't we?

Eric Berlin: Okay, so we can't do the setup. We can show you later. *Internet in a Box* is a very simple dialer. I mean, four buttons and two of which you use... *Chameleon's* is more complicated, but other companies, well, any Internet software is going to be fairly easy to set up. It doesn't matter, once you're connected, then it's just pick the tools, pick *Eudora*, *Agent*, and *Netscape*. Yes.

W: [inaudible]

Andrew Kantor: Why doesn't *Netscape* have a dialer built-in? *Netscape* now has what's called *Netscape Navigator Personal Edition*, where they bought someone's dialer and packaged it. They also package the freeware version of *Eudora*, so you get *Eudora* and *Netscape* and a dialer. I don't know, maybe they just didn't bother to do the programming, so they bought someone else's. They package it with it. So if you go to the *Netscape* booth, you can buy the personal edition, which includes a dialer.

Eric Berlin: You can, in fact, read newsgroups with *Netscape* but it's not very attractive. It's better to go through a program specialized for UseNet news. So *Netscape* thought, well, you can read news, figuring *Netscape* and *Eudora* is all you need, and that's why it did that. But without a newsreader...

Andrew Kantor: You won't UseNet news.

W: [inaudible]

Andrew Kantor: You can send e-mail if...well, the new version of *Netscape* is supposed to do e-mail, it doesn't do it very well, and with *Netscape*, if you come to a Web page that has an e-mail link built-in, like mine, if you click there, it says, "Send me e-mail" and you click there and then *Netscape* will let you send e-mail.

Eric Berlin: You can't receive e-mail.

Andrew Kantor: Yeah, you can't receive e-mail with *Netscape*.

W: [inaudible]

Andrew Kantor: The question is a comment on how we read news on UseNet. When we say news, UseNet news is simply what it's called. It's not exactly UPI and it's not news like you would find in a newspaper. It's simply a bunch of messages that people are leaving for one another. It's a bulletin board system, it is not the daily news.

Andrew Kantor: I have a few newsgroups that I follow every day, and I go check it — just news about the Internet and some other general stuff that I look at every day, see what new news is up there. If there are any that are interesting, if anyone talks about the magazine or something, I reply to it. So every day I check three or four newsgroups, see if there are messages I'm interested in, discussions I want to get into.

Eric Berlin: Why don't we make that our first thing: How do you find actual news items on the Internet? Do you want to do that?

Andrew Kantor: Actually I know some people have questions, so why don't we do that later. There are companies that will send you e-mail periodically, that sell AP; they have an AP news feeder or a UPI news feed. There is a company called Farcast — I'm not sure where they are based — but Farcast you subscribe and then AP news is periodically sent to you. I get it every two hours, I get the latest AP news. If a big news break comes in, they'll send it to me immediately. I can search the AP news feed, and Reuters, and UPI also.

That's one way I get actually real news through the Internet. So I don't have to go home and watch TV and have my mind sucked out of my head, I just read the AP news as it comes

through. If there is something interesting, I can search all of AP news for a term. So if you search on Bosnia, it will say here are articles on Bosnia in the past year.

W: [inaudible]

Andrew Kantor: Question about tools, okay. The question is, is there a provider that gives you reasonable tools. Now I don't know if you're mixing up providers...

W: [inaudible]

Andrew Kantor: Is there a software company that gives you the reasonable tools for everything? *Internet in a Box's* tools are very good. They are not the best you can get. Wollongong makes a product called *Emissary*. *Emissary* also has very good products. Actually all of them, like Quarterdeck's *Internet Suite*. They're all good.

In other words, you're not going to buy a commercial product nowadays and go, "yuck." It's very unlikely you're going to go, yuck. But there are better things than what they've got. So if you just want to buy, and you don't want to worry about searching for other stuff, you just want to get it, any of these products is going to be good.

Spry e-mail, which comes with *Internet in a Box*, is a decent program, it's not bad at all. You'll use it and you'll be happy. It's only that once you've used *Eudora*, then you say, "oh, wow, this is much better."

M: [inaudible]

Andrew Kantor: Some service providers will sell you for a buck an entire suite of software, but first of all make sure it's a suite you like. Read the reviews in the magazine, or just see if they demonstrate it to see if you like it.

Many providers, as I mentioned before, will offer software, they will give you a freeware package they've put together, they'll help you set it up. That's a very good way of getting software, without actually paying for it or downloading it.

Some providers will give you commercial software; they make a deal with a company and they say, sign up with us and we will give you the free software. It's kind of like buying your cellular phone — you sign up for cellular phone service and we'll give you the telephone for free. It's kind of like signing up with our access service and we will give you the software. That's the way a lot providers do it. It's another way to get software.

(What did you do? Why don't you just put on never hang up. Why don't you just click on...?)

Eric Berlin: No, I think seven hours should cover it.

Andrew Kantor: If it doesn't, we're all in big trouble.

Eric Berlin: There was a man here who wanted to know about finding government information.

Andrew Kantor: There he is. Okay, why don't we start with that. We're looking at different ways to find...

M: [inaudible]

Andrew Kantor: Should we make an example?

Eric Berlin: Or you can tell us a real one.

Andrew Kantor: See we have to repeat every question, because this is being taped, so we have to repeat everything into the microphone.

M: [inaudible]

Andrew Kantor: You're interested in doing some research on crashworthiness of vehicles.

M: [inaudible]

Andrew Kantor: You're a lawyer, right? I'm sorry. Obligatory, I had to do that. Okay: crash-test worthiness.

M: [inaudible]

Andrew Kantor: We're looking for highway crash [statistics] on cars; okay, stop, we don't have to put every term in here. Let's see if we can find anything on that. You don't want to be so specific.

Do we have anything on this? This is a thing I might do, and this is a tip — if you give me the acronym again, I might search www.thatacronym.gov. Let's see if *Open Text* finds it. (I really would like to use the other computer for this, the faster one.)

Eric Berlin: It's better not to switch back and forth. We have the news feed on this one. Assuming we are going to need the news people. We're getting something — we're getting a lot.

Andrew Kantor: There is an alternative to the plain old phone line. The alternative is called ISDN. I don't know if you've heard of this — Integrated Services Digital Network. That gives you an incredibly fast connection, a digital connection; instead of a 28.8 modem, it's the equivalent of 128 kilobits per second, instead of 28 kilobits per second.

A lot of phone Internet providers support it; most phone companies charge about the same rate as a telephone service to install it and to hook you up. ISDN is sweeping the country, slowly, but still sweeping the country. Hopefully, everyone will soon have that kind of connection, or maybe a connection through your cable TV.

Everyone now wants to get into the Internet business. There is company upstairs called Direct PC which gives you a satellite dish and gives you a satellite connection, which is really, really fast.

Okay, we searched on national highway traffic; we found 65 pages. That's good: it's not too much, it's not too little. The first one is a Gopher menu.

Eric Berlin: Let's see what it has here.

Andrew Kantor: DOT phone directory — Department of Transportation.

Eric Berlin: National Highway Traffic Safety, Administration Information, Office of INS.

Andrew Kantor: Office of Inspector General.

Eric Berlin: Now, say that *Open Text* allows you to do, which is wonderful, is that you can see the matches on the page without necessarily going there. So if you just blip over there to see where it matches up and then you can just come right back, and say, "okay, that wasn't it. Let's move on."

Andrew Kantor: *Open Text* index. Oh, there is no punctuation, which is a problem. National Highway Safety and Information.

Eric Berlin: Well, that sure didn't...

Andrew Kantor: Go back and go to the page; go to the Gopher menu. Now remember I mentioned that Gopher is just a list of menus, just a list of text. Now *Netscape*, which lets you see the Web, also lets you see Gopher, the Gopher menu. See, it's just a list.

Eric Berlin: Okay, Department of Transportation phone directory; General Dial Information; New Announcements; Federal Aviation Administration; National Highway Traffic Safety Information. Now let's see what they have. Server return, no data.

M: [inaudible]

Andrew Kantor: They are union, it's break time. Okay, I want to look up and I... Stop.

Eric Berlin: [inaudible]

Andrew Kantor: I look up and I see... now notice that Web addresses start with `http://`. This starts with `gopher://` — it's a Gopher menu. Just for the heck of it, I would delete that Gopher and make it `http`, or try instead of `gopher.dot.`, I'd make it `www`. And I'd get rid of that one on the end. Let's see if the DOT has a page.

Eric Berlin: The U.S. Department of Transportation.

Andrew Kantor: Well, they also have a Web page, so if you find a Gopher menu, look at the address, and substitute `www`.

Welcome to the DOT WWW server. Our government just loves acronyms. That's the symbol for the Klingon Empire. It is!

Eric Berlin: Now if you are on a dial-up connection and you want to find your information, and you don't care what the Department of Transportation's logo looks like, you could just hit stop.

Andrew Kantor: See, I've had a call from a magazine called *Log-Out*, which is the humor page, and I've looked for stuff like this. So I just got my next column.

Eric Berlin: Here, where the pictures would have loaded in...had we allowed them to load in... But we don't want that, we just want the information.

Andrew Kantor: Text links, DOT General Information, blah blah blah, Browse General Information. Useful Internet Sites, Dot Talk, Help, What's New. You've reached the Home Page

for the U.S. Department of Transportation WorldWide Web server. This server is still under construction, and new sections are being added on a continuing basis. Now if I wasn't sitting here in front of an audience of — how ever many — 60 people, I'd be going through this stuff a lot faster in terms of search.

Okay, this isn't what I want. I go back, search something else. So although it seems to take long here, in real life it's not quite as bad.

Eric Berlin: Browsing the DOT administration, just to see if there is anything there. Maybe there is even a little search engine.

Andrew Kantor: Switch to the other machine so we can get through this faster.

Eric Berlin: Hang on a second. In the middle of this, it's not the easiest things to do. Now it's interesting that the U.S. Department of Transportation has a picture of the Concord, which is a British and French plane. I just want to point that out. Okay, National Highway Traffic Safety Information.

Eric Berlin: We're going to get... "Data Not..." or whatever, again.

Andrew Kantor: Probably not.

Eric Berlin: Oh, there we go; it's www this time.

Andrew Kantor: Now there is also a text version of this site.

Eric Berlin: Let's go to it.

Andrew Kantor: This means schmucks like us who are using a [dial-up] connection can go, okay, this is what you wanted. National Highway Transportation and Safety information.

Eric Berlin: Here is a library.

Andrew Kantor: Right, we don't care about the administrator's message. We don't care about them because we know what they are. We want to know what's in their library, so we click on that. So you get the idea — this is how we're searching for information. What we'll find, I don't know.

Eric Berlin: Traffic safety facts.

Andrew Kantor: Research and development, safety, insurance, media information, consumer information, recall and defect information, general information. Are we getting in the right direction here?

Eric Berlin: What is consumer?

Andrew Kantor: No, we're not going to do all your work for you.

M: [inaudible]

Andrew Kantor: Well, hopefully this will be faster because you don't have to deal with human beings.

M: [inaudible]

Andrew Kantor: Slow down. Highway Safety Programs, Strategic Planning, Improvement. Keep going.

Eric Berlin: We not only found the organization — I forgot what the specific question was.

M: It doesn't really matter.

Eric Berlin: Crashworthiness of cars.

Andrew Kantor: Wouldn't Ralph Nader have something like that in his site?

M: [inaudible]

Eric Berlin: Well, let's give Safety Assurance a shot. We could go through all these at length. I have a funny feeling, we'll find exactly what you're looking for. I took an educated guess. Safety Assurance. Let's see, what do we want.

Andrew Kantor: We don't want to spend too much time on each individual thing.

Eric Berlin: You get the basic idea. Here we didn't even need to go to UseNet news and ask around.

M: [inaudible]

Eric Berlin: Video, we wouldn't even bother with. Not on a dialogue.

Andrew Kantor: With a direction, Video is great. It's really cool, you can see in sounds, you can hear sounds in the real time, you can listen to the World Series broadcast in real time over the Internet. Actually, you can do that with the dial-out connection, too.

Eric Berlin: With the NetSearch, we'll just go back over there.

Andrew Kantor: This page lists the contents of the available National Highway Safety Administration, database file.

Eric Berlin: This is a raw data. They say in bold, "No search engine is being provided with this data."

Andrew Kantor: Go back. All these files are available for downloading across the Net, so double-click the database name to go to the directory which contains the compressed files. You can download these files to your computer instead of viewing them over the Web. Let's say you're paying, you're going through a provider that charges you per hour, just download it and then view it locally.

M: [inaudible]

Andrew Kantor: We can capture this, we can mail ourselves this document, we can capture this file if you want.

M: [inaudible]

Andrew Kantor: We can't capture every single link and everything that's underneath it because that could be huge amounts of things. But we can do a page.

Eric Berlin: Technical service bulletins, that database — those are two main files.

Andrew Kantor: I think generally we have a good idea.

Eric Berlin: We set you on your way here.

Andrew Kantor: It takes some time. Let's find something else. Someone over here had something.

W: [inaudible]

Andrew Kantor: Finding a job teaching in Italia, particularly Milan, particularly in the northeast end of Milan, and I want to have an apartment on the third floor. Go home. Ah, you want to do *Open Text* — we like the *Open Text* engine best.

I was telling someone before — was I telling everybody? I don't remember. If you only have two... (We have a thing, show the bookmarks for a second.) These are bookmarks you can create, right now there is one bookmark, Ryan Whitney's Home Page. These are places you go frequently, so you don't have to type in the home address. If you only have two bookmarks, you should have, in order, www.opentext.com and www.yahoo.com. Those are the two best things about finding things on the Web. *Yahoo* for browsing, *Open Text* for searching.

Eric Berlin: Let's go to country, [inaudible] just text; see what *Yahoo* has.

Andrew Kantor: I'd rather do teaching, Italy, English. I'd rather do a search on that. My first thought was to go to *Open Text* and search on the words, teaching, English, and Italy.

Eric Berlin: All right.

Andrew Kantor: Talk about laziness. If you are willing to program a little and you learn HTML, my Home Page has this thing built right into it, so I don't have to actually go to the *Open Text* page.

Eric Berlin: Actually we're going to do things a little bit differently here. A simple search isn't going to cut it, I'm going to do a power search. In the first box I'm going to put: Teaching English.

Andrew Kantor: One word at a time. Italy.

Eric Berlin: And over here Italy and/or Milan/. Let's see what we wind up with by hitting search. If you know Boolean logic, if you want to go through the ands and the ors, you can get a really complicated search. Well, we found 4,546 pages.

Andrew Kantor: Wait. AGU Home Page. What is the AGU? Do you know what the AGU is? Okay, let's go down a little, let's see what we have. There is a fall meeting program — something in Italy, in Italian. Italy, Milano.

Eric Berlin: Let's see what the matches are, because it should say [inaudible]

Andrew Kantor: So it's trying to tell you — it's in Italian. How good is your Italian?

W: Not good.

Andrew Kantor: Well, that's going to change. Okay, forget it. This is all in Italian. This may actually help us, but we will never know.

Eric Berlin: This is exactly what we need.

Andrew Kantor: If anyone speaks Italian and wants to come and translate this, we can do that. Like I said, Internet is mostly in English, but some of these countries just aren't in line yet. We thought we taught them a lesson in '45.

Eric Berlin: We need to narrow this search. How might we do that?

Andrew Kantor: I think you should do a simple search. Actually, I think you should go to the first link on that page.

Eric Berlin: Well, that didn't look very promising at all.

Andrew Kantor: What? It looked like there was an organization that helps people find teaching positions. This is what I would do...

Eric Berlin: Search on English as a second language.

Andrew Kantor: EGU Home Page. What is the EGU? Who knows what that is? It could be an organization that helps you teach, helps you find teaching job.

It's .org, so it's a nonprofit organization. International schools. There are a lot of things. We ought to start to think of the search term. What search term would you use? International school is teaching, but she wants something very specific: Milan, teaching, English. But International Schools...lick on stop.

M: [inaudible]

Andrew Kantor: Yes. I think it should be teaching, Italy, Milan, in there. Teaching English as a second language. Why don't we just do ESL?

Eric Berlin: What?

Andrew Kantor: That's going to find you programs all over the U.S. because it an American [inaudible]

Eric Berlin: Well, that's what the power search is for — then English as a second language, and then Italy. Stop whatever you're doing.

Andrew Kantor: Step away from the speaker.

Eric Berlin: So we can search for the phrase, and we're not restricted by this box. English as a second language.

Andrew Kantor: Italy.

Eric Berlin: Meanwhile, I have mail. Well, this is more promising — 59 pages.

Andrew Kantor: University of Arizona, Center of English as a second language.

Eric Berlin : Center for English as Second Language.

Andrew Kantor: Go back. Milan is important.

Eric Berlin: Okay.

Andrew Kantor: Too many cooks.

Eric Berlin: Milan, really I typed it, you just can't see it. There you go.

Andrew Kantor: Search. Now, English as a second language may be a particular thing in American schools and other schools may not call it English as a second language. So we don't know.

Eric Berlin: Eleven pages.

Andrew Kantor: This looks like it's German, because these words are huge. [Cortenhurchdoing... Unterhirschmittel...]

Eric Berlin: Well, we found the FAQ for a... What's that? Social culture Italian FAQ.

Andrew Kantor: Social culture Italian FAQ. Now, here we go to see UseNet news.

Eric Berlin: Science economy research.

Andrew Kantor: You want to teach in South Africa instead, would that be okay?

Eric Berlin: Well, let's go to the FAQ file. I wanted to see what the link was before I went somewhere. Where did that FAQ file go?

Andrew Kantor: Again, in real life this would be a much faster thing and we wouldn't be boring you by going through this and looking at every link. I would look, go right to the first couple links.

M: [inaudible]

Andrew Kantor: Yes, we searched on Milan.

M: [inaudible]

Andrew Kantor: Yes, if it's contained in there, it will be in there.

Eric Berlin: We can search for teaching.

Andrew Kantor: Teaching.

Eric Berlin: English.

Andrew Kantor: Just teaching, why be so specific?

Eric Berlin: Because I already started it.

Andrew Kantor: Search on teach.

Eric Berlin: Oops. Hey, it lied to us. How can this be? Is this still coming in? No. Weird. It doesn't make any sense.

Andrew Kantor: Okay.

Eric Berlin: I don't understand.

Andrew Kantor: All right, let me get in there.

Eric Berlin: Arrrrr, now it will find it.

Andrew Kantor: I'm getting frustrated.

Eric Berlin: What are we on here: teaching, and English, and Italy, and Milan. Science Economy Research keeps coming up.

Andrew Kantor: Now here is a directory of faculty involved with international research and education. Now this may link me to someone who does teaching in Italy, and there maybe an e-mail of someone I can write to at Emory University.

Eric Berlin: The FAQ file for social culture Italian was in eight parts. It said eight of eight. That means the FAQ file is pretty darn big. We might want to look for the entire FAQ and see if it's not in that section where it is. We might want to go to the newsgroup: Social Culture Italian.

Andrew Kantor: English, English literature. Oh, no — crash. We have the BETA version they installed on this machine.

Eric Berlin: Did you hear what I just said about going to the newsgroup? Social Culture Italian. Sometimes it takes a while.

M: [inaudible]

Eric Berlin: Oh, he is in charge. Have you not noticed that?

Andrew Kantor: I've got the word "editor" in my title.

Eric Berlin: Beg your pardon.

W: [inaudible]

Andrew Kantor: These are still connected.

Eric Berlin: It should be connected. Oh, no, this is connected; it's just not plugged into that screen.

Andrew Kantor: Okay, we're going to search on a newsgroup: Social Culture Italian.

Eric Berlin: All right, it's got 915 headers, because I have never looked at this newsgroup before. So this is going to take a short bit. Actually, the rest of the FAQ should be...if the eighth part of the FAQ is on the WorldWide Web, odds are the other seven were there as well.

Andrew Kantor: We will see it when we go back the Web on this machine, is that what you are saying?

Eric Berlin: I'm making suggestions here. One small problem with Social Culture Italian is that it's in Italian.

Andrew Kantor: I'm going to look to try to find "teach."

W: [inaudible]

Eric Berlin: It's under edit, and then find. But we know there is keyboard shortcut — Control-F. We've got it down to a science.

Andrew Kantor: How do you say teach in Italian?

M: [inaudible]

Eric Berlin: That's not Italian, that's Spanish. Now everybody here speaks Italian.

Andrew Kantor: Let me go back.

Eric Berlin: This is most aggravating.

Andrew Kantor: The thing is you have to a good attention span; you have to go through each of these things one at a time and look.

Eric Berlin: Did you say that you actually speak Italian? Do you speak Italian? You don't speak Italian. So the search with that newsgroup will be of no use to you whatsoever. Which, of course, means that's where the answer is.

Andrew Kantor: Actually that's a name, I see Milan. That's someone's name, so it's not the Milan we want.

Eric Berlin: No, especially... he is a poet, evidently. What?

M: [inaudible]

Eric Berlin: Stop, stop, planned languages, excluding Esperanto. What is a planned language?

Andrew Kantor: It's probably languages they're planning to teach.

Eric Berlin: All right, so the one for one, is basically what it comes down. I mean, one for two.

Andrew Kantor: [inaudible]

Eric Berlin: I'm not sure job will do it, anymore than looking for a job to teach in Italy. Yeah, that's probably part of Gutenberg, which attempts to put every great piece of work [on-line].

Andrew Kantor: Achtung, Gutenberg.

Eric Berlin: Oh, really?

W: [inaudible]

Andrew Kantor: Oh, yes, we could.

Eric Berlin: How about North Milan?

M: [inaudible]

Eric Berlin: It's at all of those words, not necessarily in that order. Is that an orchard? Do it on a simple search. Yes?

W: [inaudible]

Eric Berlin: Teaching English abroad. I think that we're going to give up in about a second and move on to something else.

Andrew Kantor: Well, I would. Okay, so we go through this, we get to the point of being frustrated, we're not finding anything, what do we do? We go to the Social Culture Italian newsgroup and we say...first we go through and we take the time to load that long list of files in there, to look at the FAQ file.

Eric Berlin: We see it's in Italian; it's of no use to us.

Andrew Kantor: Not necessarily, if we [inaudible], we can throw it out. If not, chances are it's not going to be in English. We post a message, if we don't have the questions and answers: "Hi, I'm interested in teaching opportunities in Milan. Teaching English in Milan. Do you know...?"

So it's going from the general [to the specific]. If you can't find anything general about teaching English in Milan, you go to the specific UseNet news, and you post a message.

Eric Berlin: Even though we can't speak Italian, we're pretty sure that the people who read that newsgroup can speak English, at least somewhat. That will probably get an answer. "Looking for work? Try the World."

[Tape change]

Eric Berlin: ...post to Social culture Italian. We're not going to have enough time. So that's what we would do, if we had the time to do that. Then once you get yourself connected to the Net next week, that's what we recommend that you. It's time to let it go.

Andrew Kantor: I'm going to be yelled at for not using the microphone. Something else?

M: Starting a lottery in Belize.

Eric Berlin: Starting a lottery in Belize; you want to compete with the one in Liechtenstein. Oh boy, starting one? So therefore we need U.S. regulations.

Andrew Kantor: Okay, go to *Open Text*.

Eric Berlin: So what we want there are Internet servers.

Andrew Kantor: The thing is starting a lottery in Belize, there is no...it's not a good question. It's like how do I start a lottery in Belize? It's like how do I buy a house? There is too much information there. You have to find out exactly what you want to do. Who asked the question?

Eric Berlin: But we know who you have to ask the information too, and that is an Internet access provider in Belize.

Andrew Kantor: That's one thing to look for. Well, you don't necessarily need an access provider in Belize. The question is too general, that's the problem. It's like, well, what do you have to do to start a lottery? You want to find out, what do you need to do to start a lottery? What are the laws involved? It's something more than we could do in the next five minutes. It's too involved.

Eric Berlin: No, we still have time.

Andrew Kantor: Yes.

M: I'd like to know from the list of magazines published in the United States any with the word natural in the title.

Andrew Kantor: A list of magazines with the word natural in the title, that's easy.

Eric Berlin: Yeah. Magazine and natural on *Open Text*.

Andrew Kantor: I would go to *Yahoo* and I would search on... Entertainment magazines, let's see, do you want Magazines On Electronics; you want a list of every magazine. In that case, this is not going to work because there are going to be a million pages. Right?

Eric Berlin: What do you need, titles or...?

Andrew Kantor: You need to find a list of [magazines] which have some media on the Internet.

Eric Berlin: What follows is a list of newspapers and other mass media which have some outlets on the Internet. Natural born killjoy. There is an organization on the Internet, the electronic newsstand, you sort of link for — it briefly flashed by. They have agreements with various magazines to sell subscriptions through their server. I think you actually sample some things. We can go here — electronic newsstand. At least, see what's there as a start. Because they are expanding every day; they've got a lot of magazines under their heading.

M: What if you push title and you search for words?

Eric Berlin: It probably wouldn't be under titles.

Andrew Kantor: What you want to do is find a list of magazines, and then search those lists of magazines for the word "natural."

Eric Berlin: MagNet, that's kind of cute.

Andrew Kantor: Magazine titles alphabetically.

Eric Berlin: They are not natural looking — though it's going to be the first word, unfortunately.

Andrew Kantor: Right, so it's tough.

Eric Berlin: Wait, we just searched this under title to start; you can search this whole thing for the word natural.

Andrew Kantor: So they have all of them right here... So. natural help, that's it?

Eric Berlin: Natural help, there you have it. Next question.

Andrew Kantor: This is not every magazine in the world.

Eric Berlin: Obviously not. What you should do is try different resources. MagNet gives you this one — Electronic Newsstand. Try Electronic Newsstand.

Andrew Kantor: Now I could search on Electronic Newsstand and try to find... I know from memory that it's www.eneews.com. I could go to *Open Text*, search on Electronic Newsstand, and it would give me a lengthy list. The Electronic Newsstand. Clicked on it.

Eric Berlin: And they do it because so few people... most people subscribe to magazines the old-fashioned way. You can actually get good bargains on the Electronic Newsstand. You can probably get a better price sometimes.

Andrew Kantor: This will take some time to come in.

Eric Berlin: There is the whole list.

Andrew Kantor: From [*Agnia*] to *Yoga Journal*. Well, that's interesting, nothing has the word natural in it.

Eric Berlin: Are you certain that there are magazines that have the word natural in it?

M: Next question.

Andrew Kantor: Yeah, next question. Give us something specific that you want to do, as opposed to this bit of information you want to find.

W: [inaudible]

Eric Berlin: A list of all the domain names?

Andrew Kantor: What you can do... There is an Internet command called "who is" — it's a UNIX command. The best thing is to ask someone who knows UNIX, and you can do a "who is" search on any name you want. So you can do: Who is andrew.com, and it will tell you if it's not registered, it will say, "no matches to this name."

W: [inaudible]

Andrew Kantor: You can call the InterNIC or try to get in touch with them and see if they'll send it to you, but it's so huge.

W: [inaudible]

Andrew Kantor: It's probably out there. I guess we could search for it.

Eric Berlin: Yes. InterNIC has a Web site, but I don't know if they have... it's more like how to register and it's not a list of domain names. I'm sure there is a list out there, but it's easier if people just do a "who is" to find out if something is registered or not.

W: [inaudible]

Andrew Kantor: Yeah, if it is registered. If "who is" finds it, then you can't use it. It may not be in use yet. But if they find it, you can't use it.

Eric Berlin: Any questions?

M: Is there a Web site for dragging down different [inaudible]?

Eric Berlin: Yes, there is.

Andrew Kantor: Yes, there definitely is. I avoid plurals as much as possible. Because it gives me better search results. So I search on missing person. There may be a magazine called missing person, or a movie, or a book, or something like that that I might find. What we are trying to get you to get out of all this is that searching on the Internet, it's not perfect, and sometimes you are going to find a million links to something and none will be what you want. In which case there is always UseNet news — post on it and ask a question in the appropriate newsgroup.

Eric Berlin: There is a hierarchy. We talk about the hierarchies on UseNet news. There is the "alt" hierarchy, which is just sort of random, weird newsgroup, etc. There is one hierarchy called news, which is a very important hierarchy for the beginner. There is news.lists, which has periodically a list of every publicly available mailing list that you can join. That's a very important resource. There is news.new users questions, which is the place to go to ask a question about using UseNet news.

A lot "newbies," as they are called, simply post, How do I do such and such, in the very first newsgroup alphabetically. As a matter of fact, they set up a few bogus newsgroups at the very, very top of that list in order to catch such things. But the place for questions, the place where you are going to get polite answers as opposed to pained e-mail, is news.new, user's questions.

Andrew Kantor: It's in Elements, it's in there under UseNet news, you'll see it there. I went to one page, by the way, as you see. Currently missing, Morgan Nick. Well, assuming that there are more people missing in the country than Morgan Nick at this point... could be homeless, missing persons project. That's why it's hit or miss.

Eric Berlin: There are several missing person pages, even if they don't all link up to one another. Almost in Paradise. Almost in Paradise, but he has a computer in a Web page.

Andrew Kantor: Yeah, he is using Santa Monica's public electronic network. Let's try, missing persons, following [inaudible] prominent missing person cases, investigations with Halifax Police Department.

Eric Berlin: This is the unofficial Home Page of the Homeless and Missing Persons Network, a subgroup of a National [inaudible] and the Mentally Ill.

Andrew Kantor: You can search on anything, this is what it comes down to. Searching for stuff on the Internet — it's the same pattern. Start with the Web, start with *Open Text* or *Yahoo*, or *Lycos*, or *WebCrawler*, or one of these search engines. Look for general information on a subject, see if it's there. If it is not there, look in UseNet news, see if it's discussed in the appropriate newsgroup. If you go to that list of newsgroups...but you are not going to let me do it, are you?

Eric Berlin: What?

Andrew Kantor: You are not going to let me go to that list of newsgroups; we have to switch to the other computer?

Eric Berlin: Switch to the other computer; it takes a second and a half.

Andrew Kantor: Then I go to this list here — groups, all groups, okay. I wonder if there is a missing persons newsgroup?

W: [inaudible]

Eric Berlin: The FAQ file... They are posted periodically to the newsgroup in question. Most of them, if not all of them, are on the Web. So just as I searched on rollerblading and FAQ, I was taken right to the rollerblading FAQ.

M: [inaudible]

Eric Berlin: Some of the larger ones have many, many parts. You saw that that rollerblading FAQ was about 13 different parts, so you might wind up with different menu entries for different sections. But in general, yes, you just get taken right to it. Assuming, of course, that it exists in the first place and is on the Web.

Andrew Kantor: So, there is all missing adults; request information has searchers on a lost love — “looking for Babs from Nigeria.” So people are talking about missing people.

Now this is this family’s book about where they are getting the guy’s social security number and stuff like that. It appeared in this newsgroup: alt.missing kids.

Eric Berlin: Did we not post to a newsgroup?

Andrew Kantor: Posting is easy.

Eric Berlin: No, we did not.

Andrew Kantor: I used one of the test newsgroups.

Eric Berlin: We sort of filled alt.missing kids automatically, because that’s the newsgroup we were reading.

Andrew Kantor: I [inaudible] e-mail.

Eric Berlin: I say ignore this test or I’m going to get barraged with e-mail. Here is the subject header. I’m going to get 70 zillion e-mail messages now.

Andrew Kantor: Well, what will happen is you will get messages from computers all over the world saying, got your test, got your test, got your test. Yes, you need a news feed, you need Agent or some newsreader which will give you the list of newsgroups that are out there. Then you can go through this list. In this case *Free Agent* makes it easy. I click on groups, other things — it is like list of all newsgroups. Do you have a newsreader on this thing?

Eric Berlin: Yes I do, as a matter of fact.

Andrew Kantor: Something very bad has happened.

Eric Berlin: No, I just go down to the bottom. Go down, move all the way to the bottom. There we go. No, it’s Start Programs — I know where it is.

Andrew Kantor: Why don't you tell me.

Eric Berlin: Now we have a brief introduction to Windows 95. This is the browser.

Andrew Kantor: Spry's newsreader, which isn't bad.

Eric Berlin: Oh, it's not configured for PANIX.

Andrew Kantor: So Spry has the newsgroup browser. Same thing.

Eric Berlin: It's lots and lots and lots of newsgroups.

Andrew Kantor: So here I have my list of all groups. Whatever I'm interested in... you know, if it's Italian, I can search on that — Social Culture Italian. See if there is anything else. Trial [inaudible] — I guess this is a trial newsgroup. Just those two.

So whatever you want, you can search through your UseNet newsgroup list. Different UseNet software, different UseNet programs will give you different ways of searching through a list of all the groups. But you can do that. The important thing in searching the Internet... Just remember, think this mantra — search the Web for general, UseNet for particular — just over and over again.

Then through those two you might find e-mail addresses of people to write to, if you are interested in keeping up with a subject, like other people who are teaching Italian in Milan. You're supposed to look up...there you go. Other people, you can find maybe a mailing list; and elements gives you instructions on getting a list of mailing lists.

But maybe there is a mailing list on other people who are teaching abroad, and you want to get involved with them and exchange messages with them. One nice thing about a mailing list as opposed to UseNet news, although they tend to be smaller, is on UseNet anybody can post anything they want to the newsgroup. Mailing lists, if you post things inappropriately, they will take you off the list. So mailing lists tend to be more on subject than UseNet news. UseNet news has a lot of noise with it. All right, let's go back now. There is question here.

M: [inaudible]

Andrew Kantor: What do you mean, charged for the services that we're looking at?

M: [inaudible]

Andrew Kantor: Can you be charged for something without knowing it.

Eric Berlin: Not without knowing it, no.

Andrew Kantor: They have no way to bill you. If you go to a store, you want to buy something, you are going to have to enter in your credit card number. If you are going to sign up for a service, you are going to send them your credit card number, or send them a check. They can't bill you, they can't bill your provider, they can't bill your phone number, there is no way to bill you. So there is no way you can accidentally end up having to pay for something on the Internet.

You will know it very clearly, because it will say: Please enter your credit card number or please call us and give us your credit card number, or please mail us a check, or whatever it is. So there is nothing accidental, even with the pay services, there are free trials. You never have to worry about, for example, accidentally going over your free trial limit. They will cancel you. Like in your hotel, if you watch a free trial of a movie and you watch it for six minutes, they will bill you for it. There is none of that on the Internet. You will know if you have to pay for something.

M: [inaudible]

Andrew Kantor: The question is private investigators, he hears, are using the Internet and the Web to search for people who owe other people money, or just to find people. Yeah, it's being used. We had an article a couple of issues ago from a private investigator talking about how he uses the Internet to track people down because there are so many databases out there that are accessible, and you can even look to see if someone is posting a message.

The ways to search UseNet news for people, people who are posting... oh, well, there is the person, now he is in Albuquerque. That kind of thing. So private investigators are definitely using the Internet. If you have contacts and you really know what you're doing — and I don't, I'm not a private investigator — you can do what these people are doing about the e-mail [inaudible]. Get their social security number, where they work, all that kind of stuff. I mean, what came out from this guy... (Do you have it on here, that message I sent you, by any chance?)

Eric Berlin: I don't know if I have it or not.

Andrew Kantor: Because it's really worth seeing.

Eric Berlin: I don't think that I do. They found that social security number and all this stuff... Let's not forget that the Internet does not have every piece of information out there. Somebody came up to me at one seminar and said, "How can I use the Internet to find Virginia's state flower?" And I said, "Don't bother. Just post it in an almanac." It's much, much easier. The Internet is simply not for things like that. You can do it, I'm sure it's out there, but it's just ever so much easier just to look in an almanac.

Andrew Kantor: If you are interested, when this is done, I can show you just the information they pulled up on one person. The Internet is not going to give you abilities that you don't normally have. I mean, if you're a moron and don't know how to search for things in the library, you're probably not going to be able to find anything on the Internet that much more easily.

But the Internet gives you a lot more tools and it gives you a lot more information to search through. Before we go, we want to talk about ways you can learn more. Where you should go for more information after this. Besides the obvious solution, which is out there. Okay. Books to read that we recommend.

Eric Berlin: Is this in the *Elements* already?

Andrew Kantor: Some of this is in the *Elements*.

Eric Berlin: One that's probably not there is sort of the expended version of *Elements*. The diluted version.

Andrew Kantor: We can talk someday about dealing with publishers and how I'll never write a book again. *Internet World's 60-Minute Guide to the Internet* — it's my book, it's being sold out there. If you find *Elements* really helpful, you may want to buy the 60-minute guide. I wish I could plug it more and say, buy it, buy it, buy it, knowing that I get a couple of bucks out of it.

But honestly, *Elements* covers most, if not all, of the important stuff in the 60-minute guide. The 60-minute guide covers a lot of UNIX, for people using that, and goes into a little more detail on some things, so you may want to take a flip through it. I'm proud of it — I mean, it's my first book. But *Elements*, the free handout, gives you most of the basic information that you need.

Another good book is the *Complete Idiots*; there is *The Dummy's guide*, and *The Idiot's Guide*. I like *The Idiot's Guide*, but *The Dummy's Guide* is also very good. *Guide to the Internet*, by Peter Kent. It's a very good beginner's book.

Eric Berlin: These are more reference books: *The Internet Complete Reference* is just that — that is, one big book.

Andrew Kantor: Anything you want to know *The Internet Complete Reference* has, and actually the second edition is coming out soon. I would wait for that. It's by [Harley Hahn] and [Rick Stout] — [Harley Hahn] is around here, very nice guy — published by Osborne in Agoura Hills. And Kevin Savetz, also a nice person. Every Internet author is a nice person, with only a few exceptions. *Your Internet Consultant*, by Kevin Savetz — it's a question and answer format book. How do I sent fax through the Internet?

Eric Berlin: It's a very well-organized book, basically organized by question. You literally look up your question in the book, and there it is in the header, and the answer is underneath it. It's very well-put-together.

Andrew Kantor: Hopefully, the only shameless plug we have here, of course, is for *Internet World* magazine. We are the first, we are by far the largest, and, of course, the best magazine about the Internet. It's designed — the magazine, for those of you who haven't read it, pick up a copy on the floor because it's free — it's designed for people who are using the Internet. It's not written for newbies, it's not written for technical experts. It's written for people in between. I'm using the Internet, how do I use the Internet for business; what's going on; what are people doing on the Internet.

So if you're completely new, you might be stumped by some of it, but there is the entry level column, which will help you. Hopefully, this course has brought you up to the level where you understand most of the magazine, and if you're a real, real technical person, you may want one of the more techie magazines, like *Web Developer*, which tells you how to create things for the WorldWide Web. It's 20 bucks a year, you can't go wrong. End of shameless plug.

So when you come down to it, the Internet is all about communication and it's about information. It combines billboard, television, telephones, paper mail, libraries, reference books — all in one thing. Which is really great because you're putting all this stuff together in one thing: here it is on your desktop. On the bad side, there is a lot there and sometimes it's tough to use and to get used to. There's so much going on that it can be a little overwhelming; it's like walking into a library for the first time.

It really is just a big bunch of computers and just a lot of stuff on those computers. It's worth every minute you spend getting used to it, playing around with it, getting connected, being frustrated, staying up until two in the morning, trying to figure out how to access a Web

site, or how come this software isn't working, calling tech support. It really is worth it, once you get on the Internet and you start using it.

The example I give is my girlfriend, who is a nurse. She makes fun of me all the time; she always pretends to have an interest in the Internet, like I pretend to have an interest in, [for example], people giving birth. It's just, you know, we do this for each other. Well, then she got Netscape in her hospital — in the staff room there is a computer and it has Netscape — and I get a call from her and she says, "How do I send e-mail?"

I'm like, "Why are you asking me this?" "Well, we have Netscape." "Really?" "Oh yeah, and I found this, and I found this, and I found this." All of a sudden she was all excited about it because the Internet was no longer this computer thing, it wasn't about computers anymore, it was about nursing because she found nursing resources.

That's the step you need to make so you understand how good the Internet is and why it is so important. It is not about computers, it is about information on any subject you can imagine, whether it's rollerblades, or cancer, or nursing, or gambling, there is information out there on the Internet. Because some of the people who are out there are interested in it also, and they'll make it available. Get past that hurdle — practice, practice, practice, and then you're on your way to Carnegie Hall. Stick with the Internet, it's a really great resource. I think that's about it.

Eric Berlin: I think it is, so I would guess that [it's time to sign off].

Andrew Kantor: Thank you all for coming. if you have any questions, or want business cards, or want talk to us, we will be here for at least another 15 to 20 minutes. Anyway, thanks for coming.

TUTORIAL THE COMPLEXITY OF SEARCH ON THE INTERNET: FINDING RELEVANT INFORMATION

SPEAKER

Christine Maxwell

Publisher and Senior Vice President, The McKinley Group

Christine Maxwell: [Welcome to this tutorial on The Complexity of] Searching the Net. What I hope that you will get out of this morning's presentation is some very useful information about how to have a more successful search experience.

Before I launch into that, I think it would be helpful for you to understand a little bit about my background and the background of the McKinley Group, for whom I am the publisher. I actually have been in the information business for over 15 years. I ran an information broker business called Research On Demand since 1982, and that experience has been extremely important in having an effect on how the McKinley Group has formulated and presented its own on-line directory. The reason that has been so seminal is because the work of Information On Demand was purely focused on helping people find information. Information about anything. It was almost like having a prescription pad for people's information ills, with everything from finding out where Einstein's brain is to the used-tire market in Korea. It's unbelievable; and to find that information was always, needless to say, an amazing challenge. As for Einstein's brain — well, we found a bit of it in U.C. Berkeley and the rest of it in western Missouri.

That was a very bizarre piece of research, but what that work really showed me was how difficult it is for people — anybody, from anywhere in the world — to actually understand how to even ask questions about what they are looking for. Most people don't exactly know what they're looking for; it sort of comes to them as they search. But when you are asking somebody else to do it you have less control, and so that is very difficult. That's one of the beauties of the Internet; it has actually put the power of searching in your hands, and that's absolutely marvelous.

But, having done that, it has also done something else. It has led us all into an Aladdin's cave where everything glistens and everything is gold for somebody. But where is your piece? There is no signpost out there that says, "Hey, this is it. This is what you're looking for!" You have to keep turning things over. And that is becoming more and more of a challenge and more and more of a problem because as the Internet grows exponentially every moment that we are sitting here, the chances of you easily finding what you are looking for are more complex.

So, of course, that is where the role of directories has come in, and that is what makes directories on the Internet so important today. When you take the term "Directories," one of the things, of course, that is very confusing about the Internet is that there are so many search tools to help you. There are literally hundreds of what are called "search engines," and then some of them are called "Web crawlers" and some of them are called "directories" and some of them are called "indexes," and it is incredibly confusing. So how do you make decisions about what to use to help you find what you are looking for?

I think it is also important at this point to say something about how the Internet has grown, and about the positions of Internet providers versus private, commercial on-line providers. By [private commercial providers] I am referring to providers like America Online and CompuServe and Prodigy, and I have always likened them to planets. Instead of calling them Neptune and Mars I call it AOL and CompuServe, because until recently they have been really planets of information unto themselves. If you wanted to get the information on that planet you

had to subscribe, as you still do today, and only sort of very reluctantly will they begin to make it possible for you to send electronic mail out to the rest of the Internet.

As the Internet has really now taken up our imagination — and particularly the part of the Internet known as the WorldWide Web — those private commercial providers have had to make their planets porous so that you can come out and visit the information on the Internet, because if they hadn't done that they wouldn't have been able to keep their client base. But their primary function in life did not start with the information on the Internet; therefore the tools by which they allow their users to come out from their planets and visit the rest of the Internet are not as easy to manipulate as those that allow you to go straight to the Internet from Internet providers who just provide the pipeline.

Today, of course, the browsers which allow you to get at the text and graphics are king: *Netscape*, *Mosaic*, etc. And then you have the kind of in-betweens; you've got *NETCOM* which has *NetCruiser*, which is a sort of full service that can give you access to the Internet but also provides a method by which you can search text and graphics. So it's a positively bewildering world out there, with lots of choices.

The other thing is that no directory will ever have absolutely everything at the time that it comes on the Internet because the Internet is growing so fast. I think towards the end of my talk I will give you some ideas of where I think all this is going, how directories are going to be changing in line with what is happening on the Internet.

One of the issues that is also important is to focus on why people are going to the Internet. It isn't yet shopping, primarily, and it isn't yet primarily looking at advertising. It still is — and I believe that it will continue to be — looking for information. That is the primary reason why we come, and in doing that there are many issues that directories today can take up to help us. They involve the issue of what directories present you with.

The directory, in the broadest sense of the word, literally means directing you to some information; but if you go into the Internet right now — and we'll talk about using it from the browser from *Netscape*, because it is the most prevalent — you are given many, many different search engines to choose from.

Now, about search engines... What is behind these directories today? I'm going to go into quite some detail about what differentiates them because it has a major impact on what information comes back to you. Search engines are this enabling technology, and companies have — they used to be just those who did it on a volunteer basis. It started off as a volunteer thing; then, of course, as the Internet has grown you've had commercial entities who have come in to really take on that role, because without some funding coming in it is very difficult to keep these things going and useful. The search engines go out to the Internet and are capable of literally slurping up Internet addresses. The issue of what makes them different, one from another, has everything to do with what intelligence they have been given in order to do what they do. At the very least they might go out to the Internet and just pull in Internet addresses, and then what you get presented with is this laundry list of hotlinks to click on. That's at the basic level where there is nothing else except the links.

Then you've got some that are able to actually catalog more than just the title and the URL, [which is] the Internet address. Some of them catalog so many words — 28 words, 36 words — and some of them are far more sophisticated and actually take all the information from an entire page, like the Home Page. And some of them are even more sophisticated than that and go beyond there, going down into the links and pulling information out.

First of all, there is an issue of the differences about how they do that; and then there is everything to do with how the taxonomies are prepared for each of those different catalogs. Taxonomy — that's not a word I was very used to saying to anybody a few years ago, even though I've been in the document delivery and the research business — but today, within the

context of the Internet, it is the difference about how those are put together, and it's going to continue to have a major, major differentiating affect between one directory and another. That's another area that I'm going to be able to show you.

Finally — and this is my last point before we actually have a little trip on-line — today you can browse, and you can ask questions of the Internet in two major ways.

The first way is that you can literally do a word search. A word search can go into two ways: it can be a “keyword” search, where you just put in one word or two words; or it can be a “phrase” search where you literally put in a sentence, like “Weather in Boston,” or something. And then it can also be a subject search. That's the “browse” search, where you go into much larger categories and click on the category of Sports or something and then make selections. Those are the two major ways you are seeing over and over again in different catalogs, and we are going to examine how they differ from each other.

Netscape presents you, right off the bat — if you hit on the “Net Search” button up at the top — with some choices. You get *Lycos*, *WebCrawler*, *DejaNews* and *Excite*. I'm going to just take you through a little bit of information about each of these and then I'm going to do some comparisons for you so that you can begin to understand, I think, more about what the differences are. When you understand what the differences are you will make better decisions about where you first go to search — and time is very important, I'm sure, to every one of you. If all of us had 99 lives we'd just sit there and search 'til the cows come home and have a wonderful time, but most of us don't have that luxury. So this is what today's presentation really is about; it's about how to help you home in and choose your search methods in a much more effective way.

Lycos certainly has the most URLs. It's absolutely giant, with millions and millions. But the problem today is that volume isn't where it's at; volume without quality is a problem today, and the *Lycos* search thing — when it searches it pulls up only a small amount of information from each URL, and it doesn't take the whole page. So it's doing its ranking, its relevancy, on a much lower proportion of information than some of the other search engines. Yes?

M: I noticed now they reformatted it to get sort of an abstract. Is that like the first 1K out of the page or something?

Christine Maxwell: Yes. It's very small. McKinley's *Magellan* does 32K of information. It's much, much larger.

M: I was just wondering if there is a reason you're skipping it [inaudible]

Christine Maxwell: No, absolutely not. I skipped it because it wasn't up at the top there. *InfoSeek* is a search engine, and it has a very strong engine behind it. It captures about three or four lines; every time you do a search with it you are going to get three to four lines of information. But it is an excellent example and we will be using it.

I've talked about *Lycos*. *WebCrawler* basically gives you the URL line and the title. It is truly a laundry list; I have always thought of it as that, and I still use it. Each one of these search engines often will give you something that the other doesn't, so they're up there for a reason and I think that it's useful to compare them. Yes?

M: [Inaudible]

Christine Maxwell: No. *DejaNews* is different in that it is pulling together all the relevant hits from newsgroups, and so it has a very useful place. *InfoSeek* does that also, but the difference

there is that *InfoSeek* gives you a limited access and then you have to pay after that to get more, whereas *DejaNews*, at least at this time, is a free service. We will go into that also.

Excite is a recent addition to the search engines and directories. It has behind it an engine called *Architext*, and it is a very strong engine. When we go more into actually what is the value-added information that they provide, you will see some rather interesting differences.

Now let's just go to *Magellan*, which is from the McKinley Group. *Magellan* has been up fairly recently, and it's the newly named database of the McKinley Group. The engine that it's running on is PLS, and it's a very strong one and a very good search engine. One of the differences that *Magellan* has is the method by which they have put machine intelligence and human intelligence together so that what the Web crawler is actually calling — it's a very choosy Web crawler, because it doesn't just slurp up everything. The other major difference is the amount of information that it actually calls while it's searching; it's 32K, which is a tremendous amount of information that it's pulling up. What that allows is that when the machine actually makes a description, it is actually able to pull a lot more information and then rank it much more appropriately so that your ability to get a more targeted search is probably going to be much higher.

W: [Inaudible]

Christine Maxwell: The only thing I can tell you is that it's extremely fast. It is actually as fast as any of the other crawlers. That's to do with the technology behind it, which is proprietary — and even if it wasn't I'm afraid my technical aspect on how these things work is that I still think they're magic. But we can go into that in a minute.

M: [Inaudible]

Christine Maxwell: *Magellan* does. It's one of the unique features of *Magellan*, that in the actual resources there is a field for language that gives you the information about whether the resource is available in other languages. And if it is, then you would be able to access it. That is one of the differences in focus of *Magellan*, that it has an international focus.

One of the things that I did want to mention, because I think that it's important, is that if you do some research into who are the organizations behind these Web crawlers and directories, who are the people who have brought them into being, there are some very interesting differences. The McKinley Group has over 50 years of international publishing in its background, in international publishing and information brokering. That adds, as I said earlier, some very, very important issues in terms of how we go about bringing information together and how the information is actually presented. When you have a publishing background, I think it does an enormous amount in really helping to bring an understanding to how people look for information and as to how it should be presented.

I thought I would take some examples now and start really doing some searching, because then you can see some real differences for yourselves and come to some real opinions. I thought we would start with "Weather in Boston." Why not? As you can see, *Magellan* allows you to literally stick in some words, so I did — "Weather in Boston." And then we are going to search *Magellan* and just click on it. It tells you that there were more than 60 records found; and what *Magellan* does, what you are getting right off the bat there, is the title of a resource. These are star ratings — which I am going to say more about later — and you can go and look at a summary of information. One of the things that is going to be very important over time is the value-added information that you get right off the bat. What is it about each of these

directories that gives you information that allows you to make a much more informed decision about whether you take the time to visit a site or not?

So, in *Magellan*, right off the bat, you get some star ratings. Now, ratings are a feature that — let's go into the summary there. This is a summary that is put together by *Magellan* and the McKinley writers to help you make a decision about whether you want to visit the site or not. If you look at it, you get keywords, you get audience fields, a description, what language it is or whether there is another language, you get who produced it, how you can contact them, whether there's a cost and whether it's a commercial site or not. You can then get some additional information about the ratings, what that average rating there is broken down into. Now, the coverage also gives you information about how complete is the coverage of that resource, bearing in mind what it says it does in life, how well organized it is, how up-to-date it is, and how easy it is to actually get at. You can, at this point within *Magellan*, go and look at some more science topics and get a whole new series.

M: I understand this summary information is taken from the [inaudible]

Christine Maxwell: Well, let me put it this way; in most cases the answer to that is yes. In *Magellan's* case, these are actually written by our "cyberwriters." That is the biggest difference, the level of human intervention that we put in. We actually go in and review and evaluate and scribe and rate each of these resources, so we actually write that information. That is not taken from the Web crawler itself. It is not a machine who did that, it's a human being.

M: [Inaudible]

Christine Maxwell: When you put in a query, "Weather in Boston," the machine went into the database and pulled out and then ranked any resources that concerned weather and Boston. Now, we have already been looking at weather resources and we happened to have put into this database resources that particularly deal with weather in Boston. That's why it's come up. We are going to do a similar search now in *InfoSeek*.

M: [Inaudible]

Christine Maxwell: Over a million sites today.

M: You have reviewed a million sites?

Christine Maxwell: No. We've reviewed and rated over 40,000 and then we have, in *Magellan*, up to a million unrated resources that have been pulled in. The reviews that are there [in the unrated resources] are not yet reviewed by our humans, they're reviewed by *Magellan* itself.

M: Who do you choose to [inaudible] in your database? Is it automatic? Do you have a crawler going out and actually searching? Do people register with you?

Christine Maxwell: Yes. The answer to both those questions is yes. We do have a crawler. As I explained, it's an issue of the combination of human and machine intelligence that we have personally, specifically devised that goes out onto the Internet and crawls the Net. But once that information is crawled, then we have a whole slew of cyberwriters who are experts in their own field who go in and then review and evaluate those resources.

M: How do you choose who will evaluate them?

Christine Maxwell: I will answer that question but I would like to go a little bit further along because otherwise I think we'll lose the thread of some others. I'll come back and answer that. Is that all right with you?

M: Sure.

Christine Maxwell: Okay. With *InfoSeek* we also searched for "Weather in Boston," so you now get Boston Weather, Weather Conditions, the MIT Meteorology Department, etc.

M: Is that an Apple feature or is that [inaudible]?

Christine Maxwell: We're on a Macintosh.

M: I know. Is it a Macintosh feature or is that a Net feature?

Christine Maxwell: That's a *Netscape* feature that allows you to — well, it's Mac, too — that allows you to have the two windows up. The point I'm making here is that *InfoSeek* gives you this amount of information and now you can go straight to the site. But in *Magellan* you have this information, you have ratings, and if you go to the summary you're going to get that detailed summary. That is a unique feature of *Magellan*. Let's go back into *InfoSeek* and go back to [Netscape's] Net Search so that we can do some other. Let's try *Lycos* now.

I want to go through this exercise because it really does help us to have some remembrance of what happens with individual directories. After we've done that we're going to go into the areas of broad category searching, but we'll stick just for the moment with some little phrases.

Lycos, as you can see, presents you [with] intelligence. Now, in the way they do an abstract, this is also machine-generated. No human beings put this together; I think if they had they would probably go nuts. The highlighted words are there, but it's really quite difficult to get into that. I mean, when you've got a lot of these things to look at it's really hard work to focus on what they're giving you there. *Lycos* have actually just bought Point Communications, which is another directory, and we will go into them a little bit more. Point Communications says that it focuses on the top 5%, but it doesn't really explain how it goes about doing that; but we can look at that a bit more later.

Okay, let's try *WebCrawler*. Now here's the laundry list that I was referring to; you know, many of the directories really don't give you too much more than that, and that's a real guessing game at this point. You might be lucky. Remember we said that we were looking for Boston? Well, [we've got] a weather page, London page I, Boston on-line — there it is down there, but you don't get any information. You've got to go into the site and decide whether that's going to help you or not.

M: Do you get a lot of replicates on this? You see the second and fourth are replicates.

Christine Maxwell: Right. Well, replicates actually are a bit of a difficult thing; you can get rid of them but it takes some extra steps within the machine to make that happen, and it's quite complex. In *Magellan* we have some of that problem at the moment. We know how to get rid of it and we're working on it, but that does happen.

M: [Inaudible]

Christine Maxwell: No, it doesn't, but that just shows you the differences of how the Web crawlers work.

Let's go into *DejaNews*. As I said, *DejaNews* is different in that it is dealing with newsgroups, but it's really interesting. I could have done this in *InfoSeek* also. *InfoSeek* does that very well. We are going to get a very long laundry list of things to look at and here you just have to choose "Rain," or anything like "Weather in Boston." You would click on that. I'm not going to go take it further, but this is what you get when you use *DejaNews* and it's a complementary — I mean, you never know, of course, whether there's going to be something useful here or not, you've just got to look. So that's a lot of looking.

M: Are you basically going to find a site on the Internet or just a note posted on the NewsNet groups?

Christine Maxwell: You would find a note posted on the NewsNet groups.

M: Something about weather in Boston like five years ago?

Christine Maxwell: Well, who knows? I don't know. We can go [with that crawler and find out]. Why don't we just click on that one that said "Weather in Boston?" I don't know, we'll see. Well, okay, there's the peril in searching.

W: This one, the object that was selected was the [inaudible] search, and I'm just wondering if the other type of search is a little better.

Christine Maxwell: It might be. I think I want to take that on when we go into the more complex search, so we'll come to it in a minute.

Okay, let's do *Excite*. Let's see if we can get excited about the weather here. [The categories that come up are] Boston, Cambridge, Summary, City of Cambridge Home Page and Boston Weather. So there certainly is — again, this is like *InfoSeek* in the sense that, again, that's what you get. You don't get any further information from them. You have to go to the site, so that doesn't tell you too much.

One of the other things that comes up which is very important, I think, is what on earth do all the directories mean when they throw out words like "reviews?" What is a review? That's an interesting question. I would not say that was a review. Some people do; they call reviews everything that they write and I find there are many, many issues there about what is a review that's really helpful to people. Any amount of information is going to help you, but the more you can get the better. Can we go back to *Magellan*?

M: That was reviewed by humans?

Christine Maxwell: No, this was reviewed by machine. A machine did that.

W: It percentages the relevancy.

Christine Maxwell: Yes.

W: Can we still see [inaudible]?

Christine Maxwell: Yes, sorry. One of the things I'd like to do is go into [the category] "Boston On-line Summary." I just want to refer a little bit more to this issue of review because I'd like you to understand a little bit more about the history of how *Magellan* reviews are actually put together.

We have been putting this database together for over two and a half years. We have had a lot of background and experience in working to make this look the way it does, and the biggest lesson that I've learned from all this is that you cannot arrive at simplicity without going through complexity first. It has been extremely difficult and we are in a constant state of change about how we put together descriptions. When we first started we actually started doing, literally, descriptions only, with information informing the user about what they could expect to find in a resource. And then, later on, we decided to put in more review information, more editorial information about the content. And so what you are going to be seeing in *Magellan* is that progression from description more to actual review. We have come to that because, again, with so much information out there it really is important that the expertise and the hours and hours of looking at thousands and thousands of resources has given us a perspective about what's available on the Internet that we think is going to be helpful to users. That is what we are doing. So when we talk about reviews, we are genuinely making a tremendous effort to provide you with that kind of information.

What I'd like to look at now is some information about "browsing," or subject searching. When is it a good idea to go that route rather than just a regular, individual word search? I want to take you through browsing categories a little bit and then I want to go back to the subjects, the individual word search, and talk a lot about how to use the power behind the search engines because these search engines, including what's behind *Magellan*, are immensely powerful. They are able to help you focus right down to some very specific searching. You don't need to know, and I never wanted to know, how that happens; but I just wanted to be able to do it. So let's just talk about browsing categories for a minute.

If you'll click into the "Browse" category of *Magellan* you're going to get about 15 major categories of information there — you know, Arts and Music, Business and Economics, Law and Criminal Justice, etc. If you leave that one up — let's go back into *Netscape* and back into "Net Directory," where we're going to have a look at the *Yahoo* browsing categories — and here are major categories from *Yahoo*. Do a new window and bring it into the *InfoSeek* categories. Categories are helpful to a point; it is very difficult because, as you can see, everybody's got a different idea of what words to use. But if you start with a category — let's go back to *Yahoo* if we could — and you wanted to find "Music," for example, if you look at the main categories, you've actually got a hard time right there. I don't know where Music is. Go back one, go back on this page. Okay, here's what you get first, right? So there you do not know where Music is. You have to guess.

M: Are the categories mutually exclusive?

Christine Maxwell: Well, that's an interesting question. In some of the directories they are, and that's a problem because instead of doing a full text search across the entire database, some of them are in a box; and if you go into the wrong box you can't find it, and there's no cross-searching. So that's another issue which helps you make some decisions about which directory might be better for you in terms of how you search. I guess what I'm saying is that right there you don't know where Music is. You would have to guess.

M: It could be "Art."

Christine Maxwell: It could be Art. Let's check Art, let's go into Art. You're right, we made a good selection. But what I'm saying is that in any one of these, in the broad categories, you've got some issues about not knowing where to start.

W: What does the "@" sign mean?

Christine Maxwell: The "@" sign is part of the... Where do you see that?

W: Right by "Music and Philosophy."

Christine Maxwell: It's a cross-listing; it means it's a cross-reference to stuff. We can click on it and we'll have a look. It takes you to "Entertainment," and then it takes you into this whole other area of stuff. What's interesting about that, actually — here you've got subcategories under "Arts and Music," and let's go into "Architecture" for a minute. I'm just going to take you through it. Now, the thing about *Magellan* is that when you go into any of these subcategories and you put in your search there, you can focus your search. You can look at these entries and you could go in there and you could say, "Architecture," and then you could actually say, "Paris," for example, and it would refocus it down for you right then and there.

M: Do those billboards change all the time?

Christine Maxwell: Yes, they do. I will say a little bit more about advertising. Of course, you are noticing that there are advertising banners appearing, and what we found was that although *Magellan* has sold its database act to Internet providers, the real key is that we want it to remain free and we want people anywhere, all the time, to be able to access that directory. In order for that to happen we have also had to introduce an advertising model because we can't do it on the Good Samaritan basis; it wouldn't last very long. The interesting thing about that is to look at how directories begin to use advertising and how they organize that in a way that still makes you want to search the directory, and doesn't make you mad about what you see. That's going to be interesting; those will be one of the criteria, perhaps, for why you go to one directory and not to another.

Here's some Architecture sites. Let's go back into *Yahoo* for a minute. Let's go into Architecture... Did we find it? No. Go back up to "Art" for a minute. There's something that is very important to understand about how *Yahoo* works, how its taxonomies — there it is. Click on Architecture for a minute. That's very interesting, because what is happening is that we've gone down three huge levels in *Yahoo*. We started at Art, then we went into Architecture, then we went into this, right? In other words, it's a hierarchical structure; it's taken you down and down and down and eventually you'll go down into Australia and come out the other end. The problem with that is that it actually can't go on doing that. It's going to break because the more information comes in, they keep adding more and more links down and after you've been doing that for about 30 minutes, the fact of the matter is, if you ask 90% of people after 30 minutes, "Do you know where you are? Do you know how to go back?" you don't because you've lost your trail. Unless you're with the Minotaur and you've got a thread with you, you won't find your way back. That is a great difference between *Magellan*, in this context, and *Yahoo*. *Magellan*'s data and taxonomy can expand with the size of the Internet. It grows out, it doesn't go down.

W: Would you make more categories at the top level rather than making more levels?

Christine Maxwell: It's cross-referencing the categories across, it's a full-text search engine. It goes right away across the database all the time. It goes for depth and breadth consistently, it doesn't just keep going down into sections. Things are not just attached to one tree.

M: *Yahoo* categories [inaudible], that's created by humans.

Christine Maxwell: Yes. They decide where things go and they keep making these categories.

M: So they've made it network by adding a cross-link as opposed to a strictly "tree" structure.

Christine Maxwell: Yes. Let's go into "Architects" for a minute and let's have a look at something. Okay. Now you're finally getting to an actual, individual resource and you're getting some information about them. But there is a tremendous difference in the human intervention that goes on here compared to what is happening in *Magellan*, for example. Let's go into *Lycos* again.

M: [Inaudible]

Christine Maxwell: Gosh, it varies enormously. *Magellan* is now getting about a million a week, and the others are, well, *Yahoo* is getting quite a bit more than that. It's several million, but it's been up a lot longer. *Lycos* is getting several million also. You know, the point is that there is some difficulty at the moment in understanding what those hits are made up of because those several million... For example, the most searched Web site on the Net today is actually *Pathfinder*, Time-Warner's site, and we'll look at that later. Now, that gets 15 million hits a week, but they've revised that down to six million because what happens is, once somebody goes in there, they click on different pages. You know, there's an issue of how you count the clicks. So it's an interesting question. There's a lot of controversy going on right now about how you count when people go where.

W: [Inaudible]

[Tape change]

Christine Maxwell: Yes. The other thing, though, that's very important is that knowing where people go within a resource, which actual page do they pull up, that's very important from an advertising point of view, of course.

M: [Inaudible]

Christine Maxwell: It's very important for us because we want to know where people are looking and we want to make sure that we give you more and more resources where you're going. I mean, there is no question that "Entertainment" and "Weather" and "Sports" are, quite apart from the "Chat" aspect, absolutely the sites the Web people are going [to] today more than anywhere else, and we have to pay attention to that.

M: A big factor in tracking your site are that proxy servers mask activity against your site by delivering pages out of the proxy's cache, so that your site never gets hit again.

Christine Maxwell: Yes, that's another issue. Once you've got it on your memory, so to speak, then you've got it there. So there are lots of issues; but, nevertheless, it's actually very exciting in terms of the information. You, as an information provider who has your site up on the Net, you are getting important information about what's happening, who's visiting your resource. This is a little bit off the track, and I'll come back to that. I think it's very important and I don't want to lose it, but I'd like to just keep going.

W: I'd like to go back to a statement you made contrasting the hierarchical approach to the breadth approach. I'm wondering if you could go into a little more detail on why the breadth approach doesn't cause you to lose your way, and tell me a little bit more about it.

Christine Maxwell: Okay. When I say it isn't breadth or depth, it's depth combined with breadth, that's what *Magellan* does. *Magellan* doesn't just do a hierarchical tree that goes down and down and down. The reason why we don't do that is because more and more information is coming on, and you can't keep going down because then you can't come back up easily.

W: I understand that. I understand. The hierarchical is very easy to understand, but I don't understand what you mean by breadth.

Christine Maxwell: What breadth means, in this context, is that if you have a search engine that has the capability to go through its entire database when you put a search in — let's go back to *Magellan* and just do something else. Plunk in "Travel for Business." Let me explain to you what's happening here because I think that might help.

W: I just think you're comparing apples and oranges, though, when you don't show *Yahoo* searching.

Christine Maxwell: I'm going to show it right now. What's happening to bring up this data is that it's gone throughout the entire database looking for the words that you have put in. It doesn't just go down into the "Travel" section or the "Business" section, it's gone everywhere.

W: [Inaudible] phrase is made up of the keywords that the various resource providers gave you.

Christine Maxwell: No, we have brought those words in. But it's not just keywords, it's the full text of the actual resource itself. We go into the pages, we don't just search the wording that we gave it or the descriptions that we wrote.

M: [Inaudible]

Christine Maxwell: That's right, exactly. Let's go to *Yahoo* right now. It offers a directory of illustrated listings for Real Estate, Travel, Marine Vehicles, Business Opportunities, Extensive City and Town... Okay, leave that up and let's go into [Netscape's] Net Search, look at *Excite* and see what it gives us, and then we'll do it in *InfoSeek*. Agents, Travel, Travel On-line, *Yahoo* Business and Economy Companies, Travel, On-line Source for Amusement, Entertainment, Business Travel... Let's see. Travel Arrangements Made and Not Delivered. Well, there is certainly some stuff here.

That's a good hit, I would say. Business Travel for University of Illinois Employees, very good. Business Traveler On-line, that's a very good hit right there, I think. That's the first set that I've seen that actually had brought to my mind some of what I thought I might be looking

for. Go into *Magellan* for a minute. I don't know if we've finished the search there. Association of Business Travelers... keep going... bus.travel.com — hold it — On-line Magazine About Business Travel. Click on the summary for a minute. On-line Magazine, Latest News. There you can see a lot of difference about — you can actually phone them, you can contact them by e-mail if you needed to.

This is *Magellan*; let's go back to *InfoSeek*. Are we in *InfoSeek* there? I think we are, aren't we? Yes. There, this is what they give you. This is *InfoSeek*. Once you've done a search you get the title and you get three lines and the URL. That's what you get from *InfoSeek*. You don't get any ratings and you don't get further information than that without actually viewing the site. If you go to *WebCrawler* — that's if you wanted a real quick-and-dirty with just lines — you can certainly get it. Business Opportunity, Financial Opportunity, FAO Travel, Business Travel Management. It's a real hodgepodge.

M: You're comparing yourself to *InfoSeek*. One of the things you're comparing is the search capabilities on the *InfoSeek* and yourself, and one of the advantages you're talking about [with] *Magellan* is the summary aspect of it. Why do you feel that it is better to have the summary when you have to get to it by a click, whereas in *InfoSeek* you can get to the actual page by a click as well?

Christine Maxwell: You can get to the actual page by a click with *Magellan*, but the summary information gives you — you can make a choice about getting more information or not, so it's just as simple. It's just that if you don't want to go into a resource [you don't have to], if you want to know more, you have a choice to know more. Here is where in any directory you are going to see, over time as they differentiate themselves, that is the issue of value-added information, and that is something that the users are going to have to tell us more about — what's useful. That's why we didn't put it all on the first page, because it's a choice issue. You may not want to, you've seen enough, you've got enough information and want to go straight to the site. You don't want to read all that; but if you do want more, you've got it.

W: [Inaudible]

Christine Maxwell: How do you get there? Just www.mckinley.com.

M: When you're doing a search, do you do the search one of two ways? Do you do keyword [inaudible] is there a crossover or is there to a certain extent [inaudible]?

Christine Maxwell: The amount of information you get back in terms of how many hits will differ, but with the actual amount of content that you get back, one or two of the directories gives you a choice there.

M: [inaudible] a concept or a keyword? *Excite* does that.

Christine Maxwell: *Excite* does that. *Magellan* does that. Let's go to *InfoSeek* for a minute and let's look at the issue of the more complex search. Let's look at the issue of how to search better. They are talking to you there about being able to come up with different words or phrases to help you do a better search, and the point is that most directories have a default. When you first put in your terms that you want to search for, for example, if you put in "Vincent Van Gogh," some directories are going to default to "or" so they'll look for Vincent or Van or Gogh. Or some of them can be made to default to Vincent or Van and Gogh, and you're

going to get different results depending on where those default things are. That can get very confusing at first, [with] capitalized words only when appropriate. When you look through all this it makes it very hard to take all that in, because what they are talking about here is that they work with something called “Boolean logic,” and that allows you to.... Yeah?

M: That concept search that architects support [inaudible] PLS, they can use a thesaurus [inaudible] the keywords into other terms. If you say Van Gogh you might also find a thesaurus [inaudible] to match other things.

Christine Maxwell: Right. That’s like “Fashion” and “Apparel,” for example, where the thesaurus puts some additional words into its searching so that you get a richer feedback than you would by just using the words that you put in. That’s what you’re talking about. Why doesn’t someone suggest a search this time? Who has got an idea for something to look for?

M: Pay for Skills.

Christine Maxwell: “Pay for Skills,” okay. I did not use the word “for.” The following is the “New England Role-Playing Organization’s School Internet List and Job Announcements,” a sampling of job opportunities. Okay, let’s do that same search in *Excite*, in *Net Search*.

M: The reason this doesn’t work very well is because “pay for” is the way the English verb is constructed, not just “pay skills.”

Christine Maxwell: Yes, but it is a good example. I mean, when people just want to say what they want to say, it is helpful to understand that maybe we should go back and try and use those words in a different way and see if we can get a better result. “Developing Employable Skills,” that looks pretty good. “High Skill, High Wage.” This is a much more relevant search there than the first one that we did. Try it on *Magellan*.

Now, what’s interesting also about *Magellan*... I just want to do this once. Go back up to the top and search. This is all the rated areas, but you can also go into the unrated *Magellan* where there are even more. Just click on “Search” and it will do the same thing again in the unrated part of the database. This is just interesting, actually. So you can see the difference between them. Okay, so these are not rated and these descriptions here are the ones that have come up by use of the machine itself, using our taxonomy and the intelligence that we have given it. So these will all get reviewed and evaluated. It goes through our system, but it hasn’t been done yet.

M: When you first do a search, you are searching [inaudible] only to 40,000 [inaudible]

Christine Maxwell: What happens is that’s what comes up first because obviously those are going to be much more likely to be the ones you’d want to look at.

M: And then you can search further for the uncharted waters.

Christine Maxwell: That’s right. Well, they’re unreviewed, they’re not uncharted. They are still selected. Let’s go back. You wanted to search — was it “Women?” I heard “Women” and I didn’t hear the rest.

W: Women in Government.

Christine Maxwell: Let's just try "Women in Government" and then we're going to go to another different thing. [Here's what comes up]: University of Maryland at College Park System, Women's Studies Database, Virtual Sisterhood, Women's Studies Programs. I don't see Government too much here at the moment. Try *Yahoo*.

M: I'm interested in a different type of search.

Christine Maxwell: Yes, I'm happy to do it.

M: [Inaudible]

Christine Maxwell: You can do a back search to get that.

W: You can find out who is pointing to you?

Christine Maxwell: Yes. If you send me e-mail, do you know how to do it? I know you can do it.

M: Well, I've done it by looking for my site using some search engines and finding —

Christine Maxwell: No, there's an easier way to do it. You can actually just put in some particular thing and it'll come up for you. I know you can do it, we've done it. If someone is interested in that, you'll have to send me e-mail at maxwell@mckinley.com. It's a very useful thing to know.

The *Yahoo* search is up. Business and Economy, Organizations, Public Interest Groups, Elections, Voter Information, League of Women Voters. Well, that's pretty good.

M: I see it's highlighting things like that contain the letters "in."

Christine Maxwell: Right. That shows you what it picked. Try that in *Magellan*... Office for Women in Politics, Women's Rights, Beijing Women Power and Change, League of Women Voters.

M: It's clear that's the best hit.

Christine Maxwell: That's the best hit there. Okay, let's have a look at the issue of reviews a bit, because there's a lot of change going on in that and I want to point those out to you so you can be aware of them. Let's go to *Lycos*.

Reviews are an area where I think you are going to find more and more change coming up. I think what's important is how the directories come up with reviews. What's behind those reviews? How do you know how they are arrived at them? If you take *Lycos* — and the reason that I wanted to look at *Lycos* is because, as I said, they've recently acquired Point Communications and Point Communications started out quite recently. Actually I think it's been up for about a year. And they talked about writing reviews of sites and I think that what you are going to find when you look at reviews and compare them... Uh-oh, we can't get in right now.

M: It should be www.lycos.com. The Carnegie-Mellon site is down.

Christine Maxwell: Right. There's a tremendously different style going on in many different places about how sites are reviewed. Many of them have a kind of glibness about them, you know, trying to entertain, perhaps, rather than inform — you know, the entertainment goes for the information. That's something that you yourselves are going to judge.

There's "Point Reviews" up there and let's go in there for a minute and see what we get. There it talks about the top 5% of reviews. Let's go in there and see what happens. It isn't very clear why it's the top 5% of those reviews; but if they've reviewed everything else and are therefore able to say that these are the top five, or they made some decisions about those... Let's go to "All Reviews." We still haven't seen any reviews. We're doing a lot of clicking here. They haven't yet amalgamated this into the Lycos data system itself. I don't know whether they will or when they will, but they haven't done that yet. So here you are, it's a nice interface. Would somebody make a choice for me? I don't mind. [How about] "Kids?"

Now, Point Communications, when it was first up, didn't have a searchable engine across it. In other words, if you went into that box and you didn't find something, it didn't search across the database for you, and you're stuck with whatever is in that box on that day. Okay, we're still choosing. Go into Parenting. Go into Baby Pages. A review, finally. Now, here they've got this percentage, this relevancy for reviewing. They give it 30 out of 50, 28 out of 50 for presentation, and 35 out of 50 for experience. I'm not quite sure what kind of experience is being rated there. Mine? Theirs? I haven't been able to find any information about how this is arrived at. What does it mean? "Passing out cigars at the office. New parents can now tell all the world about their pride and joy with the on-line birth announcement service." Well, that's actually quite fun.

M: Whose standards are being used in these various reviews? For example, in *Magellan*, whose standards are you using?

Christine Maxwell: I can tell you obviously a lot more about [how] we go about rating, and I will do that. As far as this is concerned, I can only see what I see. One of my questions is that I don't know how they arrive at those ratings. I can tell you how we arrive at our ratings.

M: What I'm saying is, is there no industry standards for reviewing information on the Internet?

Christine Maxwell: No, there are no industry standards. That's one of the complexities and challenges of the Internet, how standards get created. One of the things that *Magellan* is working on is developing a standard of ratings and how we go about doing that. How do we do the ratings that we do? I can only tell you the details about that because the issue of standards is very important, the issue of consistency. What is it that you are rating?

M: Do you work with someone like the American Library Association?

Christine Maxwell: What we do is we do the following: first of all, the taxonomy that we created was originally based on the Library of Congress classification system. Then we worked very closely with the American Society for Indexes to work on how to make that taxonomy something that wasn't just a figment of our imagination. It's very easy to be sort of opportunistic and say, "Oh, let's put this here, let's put that there." It was done in a very consistent way. When we went into rating — and let me pull up our rating system for a minute, because it's easier to show it to you...

M: Are you going to mention the Advisory Board?

Christine Maxwell: Yes, I'm going to mention the Advisory Board, thank you.

Just click on *Magellan* for a moment. The other issue is that the way that *Magellan* rating is done is that we have an international board of advisors, and that board is very, very important to us. It is headed by Dan Lynch, the chairman and founder of InterOp, and we have invited onto our board professionals and academics from all over the world who are at the top of their fields in many, many different categories. For example, Professor [Maury Galman], the Nobel physicist who found the quark. We have Professor Neville Postlewaite who was the head director on the International Encyclopedia for Education. And it is that expertise that, again, comes from our international publishing background.

I worked as a director of marketing and a director of Pergum and Press Publishers for over 20 years, and Pergum and Press itself had over 500 of the top review journals, and every one of those journals had editorial boards. Those editors are extremely important in terms of formulating a bridge between all the best of publishing in the conventional sense and what is happening on the Internet today.

So the establishment of standards is very, very important. If you look at how we go about doing a rating — [we'll go] into "Women, Power and Change, Beijing 1995." It has an average there of a four-star [rating], and we are actually moving forward in that rating system. I'm the publisher for the McKinley Group. I set the standards and I set the policy by which we started our ratings, and let me give you a little bit of a background on that because I think it answers your question, at least about us.

When we first started rating I was very concerned to ensure that what we rated was very factual information, because I didn't feel at the beginning of our process that we had enough experience ourselves in being able to say, "Oh, this is the greatest site since sliced bread." Who the hell were we to say that? I mean, a lot of people think they can say that, and indeed they do. But I didn't feel that we, the McKinley Group when we first started out, had that background; so I thought it was much more important to look at the facts so that the facts were not "editorial make-up."

So the first thing that we rated was coverage. What we're trying to do there with that rating is to say, look, this site says it is the "Beijing Conference on Women." That's its content. Does it deserve the top-star rating because it covers the breadth and depth of that content? In our opinion, having looked at that site, does it or does it not? But that's what this rating breakdown is about and that's how we arrive at it, okay? For example, there are many sites that are very poorly named. There are sites, for example, that call themselves "The Pacific Rim." Oh, terrific. And you go in and what's it all about? It's just Japan. Well, that's marvelous for Japan but it's hopeless for the Pacific Rim. It is not going to get a four-star rating from *Magellan* in that context.

The organization [of the site is an] issue. Again, that is fairly factual. How well organized is the resource? Can you find your way around it easily? Do you get a sense right from the Home Page what you're going to find? Can you click immediately on the menu system? Is it really easy to find your way around? Again, we think that is something important because it tells you something about how much time you are going to have to spend in that resource to get what you want out of it.

The up-to-date issue is an interesting issue. That up-to-datedness actually is covering two aspects of up-to-datedness. The obvious one is, how recently has the site been updated? Is it something where it was updated yesterday, last week, or is it a site where even though the content was actually written in 1947, it is still up-to-date in terms of what it tells you? So you're talking about the seminal information that you can get.

There's a marvelous resource that I always think of when I think about that. Let's do a search on "Thinking" in *Magellan*. I've looked for Thinking in other resources and I find it hard to find. Let's go up and do this because this is such a wonderful article. It was written by Danover Bush in 1947. It was in the *Atlantic*. Anyway, he wrote that article to try and encourage scientists after the bomb had gone off to think positively, to come up with new ideas; and this man foresaw Windows, he foresaw the Internet. I mean, it's an incredible read. That's what I mean by finding information that — even though it was written in 1947 — is just as valid today. So when we talk about Danover Bush, there he is, an unbelievable read. Anyway, find it in Thinking under *Magellan* [www.isg.sfu.ca], etc. That actually came out of the — what's the one where they have all the big books? I can't think of the site.

M: The Gutenberg Press?

Christine Maxwell: The Gutenberg, Gutenberg. This is buried in Gutenberg also, if you take the time to find it. But anyway, we'll come out of there. But I just wanted to make the point that it isn't just the fact that it was written yesterday.

W: [Inaudible]

Christine Maxwell: The answer to that is that we constantly re-review the resources every few months. Some sites need to be reviewed literally every couple of weeks because they change so frequently. How do we deal with that? That's an issue of technology, because technology can show you whether a site has been updated or not, so you don't have to go back and review it. If it hasn't changed you won't be able to say so much about it. So there are many, many different levels of reprocessing and re-reviewing, and I don't know the answers as to how often they are reviewed in other directories because they don't tell you. I just know that's how we do it.

W: If it hasn't changed in a certain amount of time and you think it ought to, do you then downgrade its up-to-date?

Christine Maxwell: Yes. The up-to-datedness will change but the other elements of what's actually in there won't. That's true.

M: Will its up-to-date rating be faked out by somebody just touching the page [inaudible]?

Christine Maxwell: Well, the answer to that is that if it has changed the date, it will come up for review. But we would look at the site. So you would look at it and you would tell, I mean, if the content were still the same, then it hasn't changed. So the answer is, it could cheat a little bit by actually making you bring it up; but then it hasn't been changed. So that's the answer to that.

Let's go back to the rating page that we had up.

M: Will you say there also is abuse by low-speed modems?

Christine Maxwell: Low-speed modems obviously have an issue with any browser, and that has a lot to do with how much color is showing. That's something that every directory provider, including *Magellan*, has to take into account; because not everybody's got Netscape, right?

M: Does this presentation of data so that it is easy on low-speed modem users cut into your rating?

Christine Maxwell: No, because the problem is you don't know whether someone is a low-speed modem.

M: I'm thinking about 14K.

Christine Maxwell: Right. No, there's nothing there that says — well, that's not true because at the top of them they sometimes say how many K it takes to load, right? So you might have that information, but it won't give you more than that because when there is high graphics... That's an interesting question that you raise, actually.

M: [Inaudible]

Christine Maxwell: Well, most sites actually do give you little bits of information about how many K it's going to take to load something. Go into Maximal and just open www.maximal.com. This is an interesting site because it has a tremendous amount of information. It's about who governs the Russian Federation, and it.... If you come down a minute there's a section called "Hot News" and "Hot Stuff." There it is. Go into Hot News. Now, this is an interesting resource because it shows you, if you know about it, how much information you can get from going down, because this is something that's really going to change a lot.

Right now directories sort of take you to a big blob of information and the key is that, as directories develop, they're going to take you into even more detailed information. For example, here you have some contents of stories that were actually put on Maximal through Interfax news agency in Russia, and if you click on one these stories — let's select "Communists prepare to sue Yeltsin" — you get the story. Then there's this guy here — anyway, click on that. There's his phone number. You can call him up and give him hell. For the first time Russian people can actually get at their bureaucrats. Okay, take it back, please.

M: [inaudible]

Christine Maxwell: Okay. It's a very important question, and what I can tell you about that is that today, catalogs like McKinley's *Magellan* are really intermediate steps between the fact that intelligent agents are just beginning to be around but are still a very long way off from being what they will be in the future. And by that I mean that you can go on the Internet today and there's supposed to be some intelligent agent stuff going on — for example, behind shopping. There are some shopping ["intelligent agents"] where they'll say, "Tell us what you want." [You] put in, you know, "radio clock" and you want it for \$15.00 and it will go out and find the nearest radio clock to what you've asked for. That concept is [one of] an intelligent agent who has taken your idea, taken what you wanted, and has gone off around the Internet pulling your stuff up.

But the tremendous challenge today in the issues of intelligent agents is that you eventually will be able to have your own personal intelligent agent. Instead of going into the McKinley quite in the way you do now, you would say you want anything to do with "Women and Power" and "Politics" and the agent will go off by itself and meet other agents, asking, "Are you carrying power stuff? Are you carrying politics? Yes? Thank you." It will hook it in and keep going and then finally come back with your list for you. The intelligent agents will eventually be

able to do that, but it's a very, very long way away from that at the moment in terms of being able to operate at a level and at a price that we're all going to be able to afford.

M: How are the topic search agents by [inaudible] being coupled with the [inaudible] search engines?

Christine Maxwell: Yes. The question was, really, how are intelligent agents being used, insofar as they can be at this time, within the context of the *Magellan* search engine? If you go into advanced search, this is where you can begin to get a much more focused search going, by filling in those terms there. Let's try something and then we'll do it. You can really focus your search. What's happening with the engine is that it's taking the information that you give it, and the structure by which those words are related — both from a taxonomy point of view, from a linkage of similar words because it does that — and then it ranks it by relevancy at the same time. It's those three elements going across the entire database, so that no matter where you go in, whether you go in under Art and then you suddenly say Business and something else, it will take all that information and build the search on the fly.

The algorithms by which it does that are precisely what differentiates *Magellan* from other types of search engines. PLS, of course, which is its main search engine, is the combination of our taxonomy and the intelligence that we put in there, and that gives the search that we get.

M: [Inaudible]

Christine Maxwell: Harvest is more limited. Let's look at Harvest for a minute.

M: It's in harvest.cs.colorado. They have demo brokers and they are focused by topic area like [inaudible], but they collect indexes from other people and amalgamate them.

Christine Maxwell: Yes, they do, which is some of your question a bit earlier. So does anybody do it all? This does collect and index them but it doesn't obviously have their taxonomy from below it. It can go into their indexes but it can't take the depth of each one. Let's just look at "Demonstrations and Useful Indexes," and let's go in there. Basically these different indexes let you search for documents at another level because they are going by breadth; they're going through a ton of different indexes and pulling it together, but they don't go down. They haven't pulled in, you know, 32K of information on each of those individual ones. Let's try one. Let's go into "University of Colorado." Let's try the search that we tried in the other ones. What was it? Business?

M: Women in Government.

Christine Maxwell: "Women in Government." Let's do that... Okay, here's this issue of "and" and "or" that I said before, missing punctuation, not using quotes. Let's go back and put in some proper syntax. Putting in "Women and Government" would do it.

W: I think it wants a plus.

Christine Maxwell: You think it wants a plus? Try plus. I think you have to spell it out. Let's try.

We've got to get it right. Women should be with a capital. Okay, let's try that — tricks of the trade. Wow, okay. This brings in the keywords and shows you where you'll find references to Women. Let's go into it and see if we can get something out of it.

For this particular one we went into Colorado and that's what we got. If we click on there for a minute, let me just see where it takes us. Like anything else, it's a question of time. You really do need to spend some time on each of these and figure out what they actually have as certain sub-areas. Obviously, if you are interested in looking at core stuff, this is very helpful for you.

M: [inaudible] Harvest brokers is that it keeps you from grabbing stuff because instead the site indexed all of its material and sends you a compressed index, which you can then put in your own index database for about 5% of what it would be to run a whole Web crawler yourself against those sites.

Christine Maxwell: That's a very good point. That issue of bandwidth and the issue of time, that can be a real saver in many different ways.

W: In the Web Week that we just got handed out, they have a mention about *Savvy Search* which was developed by computer scientists at the University of Colorado. It does a "spider" search and it queries *Lycos* and *Yahoo* and *InfoSeek* and displays a list of the combined results.

Christine Maxwell: So they're starting to do that. Should we try that? You'd like to see that?

M: Of all these search capabilities, where do you think the most promising technology might appear? Not necessarily in any one of those, but outside of that, that might change those [inaudible], and this whole thing on the agent side, on this intelligent agent?

Christine Maxwell: The intelligent agents and the development of intelligent agents is the single most — well, there are two things. That's very, very important. The issue of how intelligent agents get incorporated into the technologies of the Web crawlers as they exist now is [important as to] whether changes are going to come.

M: What's the most right now? What technology has the most promise or who might be working on it, in your opinion?

Christine Maxwell: In my opinion, it isn't technology alone that is going to do it, but it truly is the issue of who is combining machine intelligence and human intelligence together to make this come to be the most useful for people. Machines in and of themselves, however good they are, will never be quite as accurate as a human being can be. So really, for example, in *Magellan*, we do a tremendous amount of work to automate a lot of the information that we find, but it's the human being on top of that that looks again at that information and adds additional input that the machine cannot do. Over time comes that issue of trust, the issue of, well, who do you trust? Do you trust only the machine or do you trust the machine plus the professional input on top of that? So I honestly think that's the answer that we go with. We think that the additional input of human intelligence is [important], because in the end you can have technology that can be equally good even though it's done slightly differently; but it is the human intervention that is going to make the difference over time.

M: A couple of quick questions. You've certainly set yourself a pretty formidable task. How many people do you employ to actually review these sites and how many will you have in a year?

Christine Maxwell: We have 40 people right now in our main office in Sausalito, California. We also have individual experts who help us in rating and content evaluation from outside. We are growing very, very fast, and I can see it easily being several hundred within a year because the size of the Internet is so great. And the reason why that is so important — it's not just an issue of volume, it's a differentiating issue which I'd like to say something about because *Magellan* is going to be doing more and more of that.

The Internet is not the be-all and end-all of information. It's very easy to think that it is, but there are major, major databases of content which don't see the light of day on the Internet right now unless you happen to be an extremely savvy searcher. For example, the Dialog databases. Dialog, owned by Knight-Ridder Information, has hundreds of databases which have an archival history behind them second to none. [They have] over 150 individual newspaper databases, for example, and to be able to just go to one place and search newspapers instead of this — I mean, it's a headache and a half. I love many of the newspapers on the Internet, and they are making a tremendous effort to be more useful and more friendly and give you content, but you have to go to the *San Jose Mercury News*, you have to go to the *New York Times*, you have to go to the *Wall Street Journal* — it's a headache and a half. And yet Dialog — at the moment, if you want to search Dialog, if you haven't spent a few years searching Dialog you'll pay through the nose and die off, because you have to know Boolean Logic. You have to know it and you have to know it really well. It's like being a concert pianist; it's not enough to be an amateur pianist, [just as it's not enough to do] an amateur search on Dialog. Even though they are changing the way that they structure their pricing, it used to be on time and now it's on hits. More and more it's coming that way.

But the issue is that you are going to find that those directories that really understand and have the vision to attach content beyond what is on the Internet today are where you are going to see a real change in how directories function. Directories are the beginning, directories are the heart. But the heart of the information of the world is not yet where the Internet is at. The Internet has complementary information, newsgroups have complementary information, and that's why it's very important.

There is one other fundamental difference between what *Magellan* does and what most other directories do. Most other directories are Web directories. That is all they look at, the HTTP sites. *Magellan* looks at ListSerts, it looks at newsgroups, it looks at Gopher sites, so you're getting a much more complete picture. That's very important, because today there are still millions and millions of people who only have access to e-mail; and mailing lists, in my opinion, have got a phenomenal amount of information in them and are far more accurate than most of the Web site stuff that you can get. So that's very important. We think it's very important to provide that content about other types of resources and not just what is on the WorldWide Web.

M: Does *Magellan* have an e-mail interface?

Christine Maxwell: Yes. You can get through it through just looking at text stuff.

M: So you can e-mail requests to *Magellan*, like a search?

Christine Maxwell: Yes. You can send in your own resource to *Magellan* and have it go through its pipeline and stick it in the database.

M: Can you send a query?

Christine Maxwell: Yes, you can send a query. People do send queries.

M: [Inaudible]

Christine Maxwell: mckinley@mckinley.com. It's on the Web site. You can go straight there. We don't have time to answer all of them, of course.

M: So there's not an automated [inaudible]

Christine Maxwell: No, it's not automated.

W: [Inaudible]

Christine Maxwell: Well, they come in every form under the sun, every form and every type of question. Actually, the other point I wanted to make about human intervention is that with *Magellan* we do have a publishing criteria about what goes into our resource, and what goes into our rated area of *Magellan*. We don't rate pornographic sites; those are the sites you're not going to find in *Magellan* database. That's a decision that we made. You can find it on many other things in the Internet, but when you go into there, those are sites we do not rate.

W: Does that mean they may come up under "non-rated" or that they don't come up at all?

Christine Maxwell: They don't come up.

M: You censor it?

Christine Maxwell: It is censorship in the sense that we are saying that's not what — we have a policy. We have a guideline, a publishing policy because we don't feel that that's our place. You can find it on tons of other stuff. It's not censorship in the sense that you can't find it anywhere; we're just saying that's our directory, that's our policy. For example, there's a "Parental Guidelines" piece of software, and I think it's really important that the control over what you see is in your hands and not in the government's.

W: Well, the easy availability of pornography on the Web is slowing down.

Christine Maxwell: Exactly. So, for example, Parental Guidelines is a piece of software that takes McKinley rated information because they can put that in their database and not have to worry about it. That's another choice of yours to make when you go into directories. You can know that's where our directory is coming from on those kinds of issues.

M: [Inaudible]

Christine Maxwell: The e-mail is up at the top. You can say "Feedback" and add sites if you're going to Feedback. We're not set on this particular thing, but if we were you'd be able to go and send information.

Let's go into "What's Hot."

[Tape change]

Christine Maxwell: What was that now? Oh, let's finish that. I knew about it, but I hadn't gone into it yet. "Worldwide Resources, Academic." Click there. Let's just try it. They're coming up out of the woodwork every five minutes. One needs to keep abreast of it, and it's not an easy task. We'll never be totally on top of it, that's for sure, but I don't think anybody will.

Also, I think it's important that you're going to find that in directories, one of the areas that is going to be important in all directories is the issue of user feedback, and being able to take information.

Let's go back to — what's one that we haven't looked at for awhile? Let's go back to *Yahoo*. One of the things that's going to be very interesting is how individual directories use their sites, their actual Web sites themselves, to help users. For example, in the McKinley [browser] you've got What's Hot, you've got News and Weather and Sports, [and those have been] singled out because that's what people look at. There's a constant need on our part, as directories, to pay attention to what people are asking for or where they're going. That's why you're going to see constant changes there.

Something else that's very important that you're going to see big changes in is that as the new level of browsers come up, you are going to see a *Netscape*, for example, and very soon they're going to have a very different frame. On the right hand side there's going to be a frame that will stay still so that you'll be able to have either all the links displayed or you'll have sub-directory information sitting there and be able to change what you see in the picture. It's like a window frame, and that will stay still but what you look at will change. These browsers and the way they work are going to have a fundamental affect on how directories work. It will help directories to help you much more than right now.

We haven't talked for a moment about the RML and all the multimedia side, and how is that going to affect what directories do. That's very important also. You're going to see how to search images; that's a whole issue of the index and the ability to have — I mean, there are pieces of software today that do allow you to see what the links are behind any given page at the time you are looking at the top link, and those are very helpful and that's going to become standard, I think, on any Internet browser very soon.

I wanted to go into *Yahoo*, I think, to look at whether we could do a more complex search with them. Here's how they display how you can make a better search with them. They tell you that you can find a match in the title. Do you want to find a match in the URL or in comment line? Here's this Boolean Logic thing that I was talking about. Here's where you can really get down and get to a more focused search by — if you know the URL you could just stick it in there, if you just know the title you could put it in there. So every directory is trying hard to help you find things quicker than you can at the moment. It just takes some thinking to do this part. It's much easier to just throw in some words and get your first search back; this takes some more patience to actually take the time to go in here.

One of the things *Magellan* does, actually, is it allows you to choose how many lines of information you want to see, that issue of whether you want to see just one line at the beginning or two or three. These are all choice factors, and as the directories become more sophisticated they'll let you do that.

Let's talk about international things for a minute. One of the things that I think is very important is that with the Internet itself — everyone knows it's been global from the start, but the fact of the matter is that initially much of the content was American because most of the resources that were initially being put up were domestic. That's an area where you are seeing that things are really changing, and that you're getting a lot more content from other countries coming up very, very quickly.

There's an issue of the translations and whether automatic translation works. Well, we've looked at a lot of different translation programs ourselves because we're very concerned about the international content and about being able to present content in native language. Unfortunately, those programs don't yet work in the way that allows us to do it easily. It sounds like it should and I've seen many translation programs at different conventions, but they're just not there. They're not there for helping us to make the directory that way easily. So what we do is that we actually make it our business to take several hundreds of resources from France, and those that have already been written up in French because the sites themselves are in double language, and we're focusing on actually writing those up so that there is a base level, at least, of other language content. I think that that's a beginning, but it's only a beginning.

Just go into France, for example. Let's just try. That's another thing that's really where I think you're going to see a lot of interesting developments. People think in many, many different ways and therefore the difference between how you took a directory of information in the past and looked at it — if you look up Internet directories to date that are actually in paper format, there are some major problems with them. Much of the problems come from the fact that when you want to look at some information, if you didn't think in the same way the author thought it's hard for you to find what you're looking for half the time, because maybe you classified "Women" under "Social Sciences" and they put it in under "Health" or something, and you can't find it. Of course, within the context of the Internet, you can do that now because you have a much greater capacity to find things. But just go into any of the summaries, one of the summaries [like] EUNet France. There you are. There's that French issue there. That's going to tell you that if you go in here you will find it available also in French. That's a unique feature of *Magellan*.

The other thing that's important is the audience field. When people think of words for how can they search a site, keywords are not always — sometimes you have difficulty coming up with those. Audience fields are an interesting way of coming at information from a different way because you can think about, "Well, I am a statistician," or a nurse, or whatever. Sometimes that helps you to come with words that are going to help you find what you are looking for.

M: Are those summaries searchable? Suppose I want to find all [inaudible] French.

Christine Maxwell: Yes, yes. You will find it. Definitely.

Let's go into *Excite*. Now, if anybody wants me to search a different directory that I haven't spent time with, I'll be happy to do it. The reason why I'm focusing on these is because they are the most used right now and it gives you a good, broad brush.

Let's just stay here for a minute. Here's a company that does say it does reviews, and I think it's important to look again at how they handle that. Let's just go into "Reviews" for a minute. "Featured Review." Here it's featured one particular one. It talks about "Book Stacks" and it tells you what it is. Now that's a genuine review, in my opinion, because it actually does tell you about it. Let's go into one of their categories. Let's try "Lifestyles." It's quite helpful that they have individual things underneath it. They feature a review so they've chosen one out of all

the ones that they have done. They don't tell you why they've featured it, they've just made a selection. So here they're giving you short amounts of information. Why don't you go into "Howard Reingold," for example, and let's look at — they just say he's the editor, [and he] passes along his thoughts.

One of the tests that I think tells you a lot about how accurate reviews are is to go into your favorite site and just try each one of the directories that you focus on and look at the differences, because that tells you more than anything. I mean, I'm just showing some examples, and I know each one of you could come up with your own. A lot of the issues about what you choose to use has everything to do with what your expertise is or what your work is.

I did talk a little bit about America Online and CompuServe. I didn't say very much about them, but CompuServe, for example, has thousands of forums, business forums, that are very, very good. They're not available on the Internet and so you are going to miss out on the information if you don't belong to CompuServe, because you won't be able to get it.

So there is a lot of homework to be done in terms of really trying to assess which kind of directory, which kind of planet of information is going to have more of what you yourselves need. I'm not saying to you that any of these directories necessarily match everything that you're looking for, but I would say that one or two of them will probably meet your needs faster and more accurately than others, and that has everything to do with how they're put together.

M: Do you feel that in the future CompuServe and America Online are going to be obsolete in a way, because they're going to get so much pressure? All this stuff is free, and they're charging. What is your perspective on that?

Christine Maxwell: Right. Can you see if you can put *Pathfinder* up in the meantime? The question was, do I think that America Online and CompuServe will actually become obsolete because there's so much free information out on the Internet itself? The answer, I believe is...

M: Obsolete is a strong word.

Christine Maxwell: It is a strong word.

W: [Inaudible] what they add to their product?

Christine Maxwell: I think it depends on what they add, because the issue is what information they have that is unique to their service. That is one question. What is so attractive that people will keep coming back? But you've got to remember why people go to AOL. After all, it's a lot easier for many people to start with one of the services because they don't really have to figure out all the problems of how to connect, and what's a PPP, and [what's a] shell and a god-knows-what. That's really still a big, big problem for many, many people. So going to AOL is an easier step.

Now, the problem for AOL today, as it is for CompuServe, is not initially how to get a client, how to get a customer, but how to keep them. Customer retention is by far the hardest thing for them today. So what do they need in order to keep their customers happy? They must ensure them a really successful search experience. If they don't get stuff, if they keep clicking and then they go into something and it's not what they want and they go back out, that issue of wasting time or saving time is very, very important. That's where a really good directory has a focal point to play in the success of America Online, etc. Those companies that don't have really strong directories have got a real problem. Look at eWorld, for example. eWorld has got

a lot of catching up to do because it doesn't have a lot of content; it doesn't take people a lot of time to work their way around eWorld and then they want to get out. That's a challenge for them at this time. If you go to GNN, Global Network Navigator, there's been a lot of talk about — actually, it's part of AOL.

Can we put up a new window for a minute? I'm going to come to *Pathfinder* in a minute. I like to look at that a lot, actually, because it's so successful as a site at this point and I think there's a lot that we can learn as directory from that, and, a lot that you can also learn.

GNN prides itself on selectivity. It has about 12,000 sites that it has reviewed and evaluated. It's got a brand new look today; it hasn't been up very long like this. It's got some interesting... That's the whole Internet catalog; that's where they have their catalog, and they've got different features here. Here's how you see what different catalogs are trying to do to attract people and to keep them. They're changing the features here.

M: Like a newspaper.

Christine Maxwell: Exactly. It's getting more like a newspaper. It's pretty interesting. Let's go into their catalog for a minute because I think it's important.

W: What is the GNN map?

Christine Maxwell: Let's try it again. I tried to get in this morning, but couldn't. Great, we are getting in. [The categories that come up are] What's Up About GNN, GNN Voices, GNN News. So it gives you a bit more of a breakdown as to how it's organized.

W: Do you have to pay to use it? What does "Join GNN" mean?

Christine Maxwell: Where is it?

W: It's in the upper left.

Christine Maxwell: There we go, bulls-eye, sorry. Okay, you can become a member; if you want complete Internet access, blah, blah, blah, because it's part of AOL. But let's go back to the catalog just for one minute to see what they've done with it. They've also gone into — they have a "Best of the Web," where they have taken all their reviews and they are kind of giving it an Oscar rating or something.

[Then there's the category] "The Worst of the Web," yes sir, it's the worst of the Web. Well, the only reason why I bring this up is because what they've done here is rather than get you straight into their own catalog they've given you other places to go. So it's a catalog, but they're going to other catalogs, right? They've kind of, at least on the surface, opted out of their own. And in a sense, Point Communications, now that it's been enveloped by *Lycos*, hasn't yet put themselves together.

I think the other thing you're going to see over the coming months is this alliance stuff going on. It's going to go on fast and furious for quite a while, and the reason why that's important is because there is so much information out there. So it's very important, actually, for catalogs to look at what kind of alliance is going to help them give a better product to you. That's what it's all about, it really is.

Let's look at *Pathfinder* for a minute because I think I'm going to end on that as a sort of — it positively gives you indigestion, it's got so much information.

M: [Inaudible]

Christine Maxwell: In our context, the reason why we review sites, and how we make the selection, is this. We first of all use our machine intelligence, which is based on our human intelligence in the first place, to pull information and to pull resources in. So we're already making a selection process right there. When those resources come up they come into our — we call them "information buckets," so that "Arts and Education" will already be in the Arts and Education bucket by virtue of the way we have constructed our system. Then cyberwriters, as we call them, are the first step in the evaluation and writing process. They go into each site and they literally review the entire resource.

Now, the issue of whether they decide to write something up or not has a lot to do with many different factors. For example, if something is totally under construction it's not going to get written up at that time; it will go into the re-review process in a month or something like that. Or the Home Page itself might be thoroughly uninteresting but once you've gone down three pages, then all of a sudden there's this marvelous page there about chemical research or whatever. So that one would get written up. That's the difference between a human being doing it and just a machine. If you put in the word "hate" — I remember doing this search, it was quite a while ago and I did the search on hate in *Yahoo* — and I got "Chateau La Jolla Hotel" as the very first thing to find. Now that really shows you how a machine can go wrong if a human being doesn't look at it.

M: Is that part of the technology used to pull that in [inaudible]?

Christine Maxwell: Yes. Now with *Pathfinder*, this is the site that gets 15 million hits a week, and if you go down a little bit further there's something which says "List All Our Databases." Now you're down here a bit further and each one of these, of course, represents one of their products and we can take our pick. Let's go into "People."

Okay, here's *People* magazine. Now, what's interesting about that is that you can, if you had gone in — what would have been great, because remember *Pathfinder* is just so enormous, is if you could have just put in "Princess Diana" and it would have been great for you if, in fact, that had just come up as immediately as one of the selections [that came up just] because we just happened on it. With "People," well that's a good guess, you know, she ought to be in there. You can do some sort of educated guesses about where things are but you haven't got a lot of time, and that's a lot of educated guessing that you're going to have to do.

So the key, really, is how are directories themselves going to be able to help you find that right off the bat? The only way they're going to do that, actually, is by alliances, alliances with content providers. The big content providers, Time-Warner for example, are the people with who you're going to see a very different ownership of directories, because little directories can't survive by themselves. The [directories] don't have content; they just catalog resources on the Internet. That's a beginning, that's not an end. Where those alliances are going to come — the alliances where content comes from directories on the Internet — are what I think is going to make directories much more helpful and much more able to burrow down to content and give you strong article information just like Dialog does.

I come back to Dialog again because in my information days under Research On Demand — that's what's so interesting about [the state of the Internet] today; for 25 years, the cutting edge of information gathering was the on-line databases. It was Lexus and Nexus, it was Dialog, it was BRS, and now those tools are conventional tools in our database, in our searching. What is the front end or the cutting edge tool now? It's the Internet.

There's another tool which has immense importance within the context of the Internet, but you don't see it yet. You don't see it playing that role yet, and it's called Geographic Information Systems. It's an enabling technology that you see a lot right now in map-based marketing. Map Info, for example. The best one is put out by ESRI, the Environmental Systems Research Institute in Redlands, California. They have a system called *Ark Info*. Anyway, that technology essentially allows you to take pictures — it's like having a pictorial spreadsheet and it's an absolutely fascinating technology.

W: I don't get the connection.

Christine Maxwell: What I'm saying is that at the moment, what's happening here is that this is all relational database information, right? And the search engines are based on relational information; but that image aspect, being able to take pictures and also relate pictures and text together, that's what the GIS does.

When you build a geographic information system you have to geocode the information, and the issue of how you geocode it allows you to relate any kind of information whatsoever and bring it up on a map.

M: [Inaudible]

Christine Maxwell: Right. But I mean, here's the hotel. It isn't just a question of showing you a nice map all around that you could actually attach all kinds of information to and could see very in-depth content coming up on. You know, you would say, "inside that building it's got Xerox Park," and then you click on Xerox Park and it shows you. I mean, you can build and build levels of information, levels of image stock.

W: You could say that rather than a map you could use a different kind of image.

Christine Maxwell: Yes. So I'm just saying that the virtual reality and all the multimedia aspects of content on the Net that you can get now — and it's going to become even more visible as the Net progresses — is an immense challenge for directories because we've already got enough information right now, [so much that] we're drowning. How are we going to deal with those? Well, unless you use a technology like GIS you won't be able to do it well.

M: Are you guys working on that technology? Are there other companies working on that?

Christine Maxwell: The companies who have worked in GIS, of which I've mentioned a few — that's an area where, like everything else in life, I think you need to work with the companies who have that expertise. GIS is a very formidable, enabling technology and you need a tremendous expertise in it. But how you use it in the context of the Internet is going to be very interesting.

M: [Inaudible]

Christine Maxwell: ESRI stands for Environmental Systems Research Institute in Redlands, California. Map Info, they're up here. I think they're in Mountain View. Etak belongs to Rupert Murdoch.

W: [Inaudible]

Christine Maxwell: Atlas uses GIS in a format, but they don't have as robust an enabling technology. The robustness is terribly important, actually, because we're taking about such a volume of input.

I think the other thing that's critical when we talk about the interactive aspect of the Internet [is that] every single one of us here has a role to play in how the Internet is going to progress and whether it answers to your needs. It can only answer your needs if you really help to express what your needs are. It's a bit like voting.

Not only that, the architecture of the Net or how the Net gets built up — you know, just because it started the way it did, by being very volunteering and so on, that's an aspect of the Net that all of us have really gleaned a tremendous amount from. Just because commerce has arrived doesn't mean that all the good things that the Internet started with will go away; I don't think they will. The sharing of information, that whole aspect is something that I think the Net will always have.

Right now, when we talk about the WorldWide Web, we talk about the ability for anybody to literally hang out their shingle and say, "I am this, I am the best sweet shop on the Net, I am the place where you can get the best information for how to deal with your teething baby," or whatever it is. You can be that. Because it is as simple as literally setting up your Web page, then you yourselves can have just as much input on how to make standards happen. One of the things that I hope is finally beginning to change is that when people first started putting up Internet resources it was almost like somebody wanted to be in the Guinness Book of Records for the amount of links they put in there. It was awful. And you still get that a lot, so you lose complete sight of why somebody started their Web site in the first place.

It's very hard for directories to get it right in that context because people are so over the map. That's where the control issue comes in, really. After a while you have to take some responsibility. If you're going to put resources up then you've got to try very hard to put yourself in the role of those who are going to use that resource. That's what *Magellan* itself truly tries to do in every way, shape and form. It's not only to think about how to present information so that you will find it easier, but to think very carefully about covering every type of information and any kind of individual, whether they be from anywhere outside of the world, or from different cultures, different abilities, different age groups. All that is really important because the Internet is really a place for all of us.

So the directory does try to be something for everyone; that is its role because it's trying to be as comprehensive as possible. It's trying to include all of the areas of the Internet, in terms of different tools, etc. Can you get it just through Gopher, can you get newsgroup information, can you get FTP information? We think you should be able to do all that in a directory.

The one-stop-shop is where your intelligent agents will come in over time because it will be your personal intelligent agent. But until that time you do have to rely on directories. I think we have a big responsibility as a directory publisher to try to answer as many of your needs as possible. So the more you can let us know what your needs are, the better we will be able to serve you.

Anyway, I think that's where I'm at today. Any more questions? I'll be happy to answer them.

I have one other thing which you might like to know. This is the *McKinley Internet Yellow Pages*. It's actually the third edition of *New Writers Official Internet Yellow Pages*, which I co-authored. It's now called the *McKinley Internet Yellow Pages*. Why did we do that? We did it because we still feel that there are millions of people out there on the Internet — sorry, not on the Internet — who have not yet been on computers or are just starting the Internet, and it's

really important to help people have a way to know why they're going on the Internet, to help people to find resources so that they themselves can say, "Gosh, that's why I'm going here. I'm going here because I want to look at this resource," or "That speaks directly to me."

That's another thing. It's a complementary area, a reference book like that, and I think for a long, long time to come there still will be a need for different types of content in different formats. CD-ROM, of course, is a very big and very important area. Japan is a particular case in point where they have such difficulty with current connectivity. CD-ROM access to directories is very important for Japan more than anywhere in some ways right now.

M: Do you provide [inaudible]?

Christine Maxwell: Yes. Actually we have a CD-ROM coming out within a couple of months.

So, anyway, that's a small, quick tour of the Net and I hope I've answered some of your questions.

TUTORIALS

C++ TECHNIQUES FOR BUILDING COMMUNICATION PROTOCOL LIBRARIES

SPEAKER

Michael Baldwin

President, Dart Communications

Michael Baldwin: Good afternoon. My name is Mike Baldwin and welcome to "Tutorial 3, C++ Techniques for Building Communication Protocol Libraries." I understand we have one developer who's developed to the WinSock specification and, [since] you're probably already an expert, I'll be doing a talk on that tomorrow at 1:30 for 2-1/2 hours and these gentlemen over here? Berkeley Sockets? Were you on a PC platform or UNIX platform?

M: [inaudible].

Michael Baldwin: Okay. That's cool. My name is Mike Baldwin, like I said. There's my e-mail address if you'd like to correspond with me after the show. We have a WorldWide Web page called www.dart.com and the reason I was asked to speak today is because I've been in the business of building TCP/IP applications for a little over five years. My first experience was in 1990 using the [inaudible]. TCP/IP network interface card that had TCP on the card. My company commercialized the first WinSock TCP/IP protocol library in February, 1993. Those familiar with the WinSock specification know that it's just about the time, it was actually January of 1994 that the WinSock 1.1 spec became finalized, but we participated in that specification.

Our company, Dart Communications, has a line of communication libraries called Power TCP that were first released last summer, and we first implemented C++ class libraries, DLLs and VBXs for Telnet and TCP. Those, of course, were WinSock compliant libraries and today we've moved right along and now we support FTP simple mail transfer protocol, POP 3, UDP, VT-220, TFTP and SNMP and these are all based on our C++ class libraries, so the architecture of our products are C++ classes up to a particular point and then if our customer wants a C++ class library they take that. If they want a DLL we slap on a DLL interface so that non-Microsoft compilers can interface to it, or if our customer needs a VBX or an OCX we [inaudible] link that interface right onto the class library so the same underlying code forms the basis of all of our libraries, and I would certainly recommend that architectural approach to anyone who's building communication libraries.

M: [inaudible].

Michael Baldwin: We do not have an HTTP control because we do not feel that there was enough value-add there. There are Web clients that do the visualization which is the most difficult part, the visualization. The HTTP protocol itself is changing so rapidly it would be hard to standardize in a particular version and it is moving so rapidly that as soon as it would be released it would be obsolete because there would be 3.0 then there would be the Netscape extensions, etc. Our TCP library would allow anyone the mechanism to connect up to the HTTP port which I believe is 110 then interpret the data that is sent back and forth.

Gentleman, [please] felt free to speak. Please, we've got a small group here. Whenever you've got a question that's relevant, please we'll address it as we go along.

M: [inaudible].

Michael Baldwin: Yes, they are. There's a market forces issue. Although people have asked us about UNIX versions, our experience has been it's expensive to maintain the libraries across so many platforms, we would be forced to distribute source code which we have chosen not to do. We have found that many UNIX shops are more than happy to climb onto existing source code that's available freely on the Internet, so there wasn't as much [of a] market for us.

M: Let me ask you one quick question. Your [inaudible] classes, those are actually, you're standardized on [the] WinSock API, so those classes actually work... you have the TCP/IP layer and then WinSock represents [inaudible] then all your stuff sits on top there?

Michael Baldwin: Yes, sir.

M: So if I link your SET library for a class into my program, then my program will still function with any other WinSock.

Michael Baldwin: That's right, and it will run Windows NT, Windows 95, Windows for Workgroups, that manages stacks distinct, etc.

The goals of the session today are very much C++ related and oriented. Tomorrow's goals at 1:30, I've got the same slot in the same place, perhaps I'll see some of you here, tomorrow's goals will be to talk about the WinSock interface, the WinSock layer, more tools-oriented, standards-oriented. Today we're C++ oriented.

The mechanisms that make C++ such a very nice model for us in the communications world is, number one, class specialization. For example, if one builds a TCP class one can derive a Telnet class from TCP and incorporate the Telnet functionality without touching any of the code in the class library for the TCP library. So we have found that to be of great benefit, [so] that when we locate an interoperability problem with a vendor's WinSock stack then we [can] provide the fix in a low level base class, then that fix propagates throughout our entire product line.

Encapsulation. Kind of the flip side to class specialization. Encapsulation is where instead of deriving from the class you put an instance of that class within your class. In some places in the communication area, FTP or file transfer protocol is appropriate for doing that type of thing.

Virtual functions for event notification. Probably the most interesting and positive aspect of using C++ class libraries is that the base class can define a virtual function that is either pure virtual or not, that is meant to be overridden by the derives class or your class. So, for example, if the library would like to notify your class of an event or received data, then it can call the receive event and it just naturally gets called right in your user class or your derive class so that you can just handle it right there in your class, so you get notified of data so it's very event driven. It can also be used reciprocally in that the base class can find out the information from any derived class by using virtual functions or defining a virtual function where when it's called you provide a response. In both techniques you'll notice if you go to MFC libraries for example and see how those libraries are used to communicate windowing information to and from your derived class.

Those are the goals. Now, how are we going to do the goals? In Section 1 we'll have a review of C++ mechanisms, the specialization, encapsulation and the virtual functions that we just described just to reinforce those points. In Section 2 we'll apply those mechanisms to communication software development. I'll be using our class libraries and some of that code for

demonstration purposes. Then Section 3, I'm hoping that we'll be doing a live Microsoft Visual C demonstration using our libraries, if we can get the network interface issue resolved here.

M: [inaudible].

Michael Baldwin: I'll be showing the design of the libraries and if there is a particular implementation feature that you would like to see, I've got the make files with the source code all right here so we can review them quickly.

I debated whether or not I should bring my source code to show everybody, you know, trade secrets and all that stuff, but I'm not too worried.

M: [inaudible].

Michael Baldwin: Well, not so much that as deciding to do it. I thought it would be a very unique opportunity for those here in the room to see how professional level libraries are manufactured. The first time I saw the TCP/IP networking code that a Microsoft engineer showed me about three years ago on his PC, I was just so impressed. Oh, that's written in just regular old C? I can understand what's going on here. So I just kind of want to take the mystery out of it here.

Class Specialization. Okay, here I've illustrated a very simple situation where two class libraries illustrating double inheritance are shown to bring capabilities into your user class, so if we look here at the bottom we have a user class called class user terminal and let's say that's a Telnet terminal that you'd like to write. The way we can use class inheritance to its very best capabilities is to derive both from our communications class and from a viewer or a user interface object. So here on the left for the sake of additional information I show a base class called Power TCP and then when we derive from that class a Telnet class which basically splits the stream up into commands and data and then provides that information down to the user class where a couple virtual functions, bodies, are defined on the part of the user.

On the right side, I didn't want to show the entire MFC hierarchy, but C edit view would give you an edit window and you can derive from that so that when you don't need to specify, for example, if you gave it a name using encapsulation it would be within the class definition, you have C edit view space my terminal, or something, my edit box. Then down there in user class you would have to specify the edit box whenever you wanted to put something in it. But when you do multiple inheritance like this, you are in [the] edit box and you are a Telnet connection.

M: [inaudible] using multiple inheritance, what would be the design advantage using that instead of, for example, [inaudible] user terminal, for example, didn't have a dedicated Telnet protocol. It seems like it would be more flexible if instead of using [inaudible] inheritance, I mean, that way you're not [inaudible].

Michael Baldwin: I see, this right here is assuming that you are making a Telnet terminal, so it is not that flexible in that you can't swap different communication streams for example. So you really are hard-coding in a Telnet terminal that has the features ... so you've married these two features. It wouldn't work using a commercial library to go MFC class C edit view and then inherit base class Power TCP because in our commercial libraries we don't show C edit view as apparent to drafting that, so you couldn't do it that way. However, if you were building something yourself, it would be perfectly acceptable to put everything all in line.

M: [inaudible].

Michael Baldwin: The next slide may illustrate [inaudible] a little bit better then, perhaps, we'll come back and contrast the two views.

Using encapsulation you can do exactly the same thing. You can derive your user class from our base class, I left off the TCP class, and then using encapsulation you could have a C edit view terminal right in your user class. I think some C++ purists would say that they really like to have the object of the previous slide comprised of both. Others would say that, well, for simplicity reasons they like this approach; however, when you do it this way you're more of a switch. Your user class becomes more of a switch. It's switching data from itself, if you thought of it primarily as communications, the user Telnet, when data came in it would say terminal.cell text = or however it does it. Using the previous mechanism you would just say cell text = data, so you eliminate the reference to terminal.

M: [inaudible]

Michael Baldwin: Why not?

M: Well it doesn't seem [inaudible].

Michael Baldwin: Why not? We're pushing the paradigm. This is thinking about things a little bit differently. How many people would, how many software designers would implement communications as C++ class libraries?

M: [inaudible]

Michael Baldwin: Okay. Then why, just to go back here to this slide, an instance of the bottom class there that's a Telnet terminal and a Telnet terminal, if I was to think of a piece of hardware, basically handles the communications and displays it and sends the communications out.

M: I would say, using a communications channel [inaudible] and using a keyboard to get it, but it is not a keyboard. That's my taste, you know?

Michael Baldwin: You're right. It's personal taste and I think there is more than one way to skin a cat. I've got a ...

M: That's one way to skin a [inaudible].

Michael Baldwin: From a personal point of view, I've got a very talented young man, a C++ programmer, when he discovered that he could do this he got very excited. Paul is like that. You get excited about C++ technology, whereas in my first go around with communication libraries I actually did take the approach that you [went] as far as the data communications channel and it was more of two things talking to each other. It was not quite as elegant and not quite as clean, but you can certainly do it and implement this both ways. I will in a couple slides, we'll talk about where encapsulation perhaps makes more sense, where it has to be done that way.

Virtual functions for derived class event notification. We're going to start getting into the code here. A base class describes a virtual function called "receive event" and it points to

data and it describes the length of the data. It could be a virtual function if we put a little `=0` there at the end of the function, it could be virtual, and then you would force the derived class to always to provide the member. Then in the derived class we have a receive event that is completed within the C's or Telnet class and in that class you simply provide the code of what you wish to do with that data. So it's a very proactive type of design. There are other types of designs that give one a signal and then, the WinSock programmers here would know that, you get the signal that there is data received and then it's up to you to allocate a buffer and read the data into a buffer in order to utilize the data and the design of our class libraries basically implemented that within the library and then provide a pointer and a byte count [of] the data to the application. Very proactive, event driven.

Virtual functions for base class queries. Well, when you build it yourself, a set of libraries comprised of building blocks like this, you may have a need to get a type or find out what the type of the derived class is. So here is the mechanism, kind of in reverse, that in a base class, and our C WinSock class is the bottom most class that we use, we have a virtual function that returns a type of protocol and then down in our drive class, our Telnet protocol, it returns our Telnet type. So that's a mechanism for doing the opposite or reciprocal. So, in one mechanism we're volunteering data to the user class and the mechanism we're asking the user class what protocol it's using and we make it a pure virtual function so that at compile time we can check for any errors or any failures of that occurring.

M: Is that just a demonstrator or would you actually change the behavior of your base class [inaudible].

Michael Baldwin: Actually we use it for a licensing mechanism, because our product is licensed on a protocol basis so we want to know what protocol the user is exercising. That allows us to place all of our core technology and licensing right in a base class, [at a] very low level. It certainly has other purposes too. Any time that you want to know information about a derived class.

M: [inaudible].

Michael Baldwin: Yes, we just have an enumerated for each protocol type but this is just illustrating the technique. For your own application you may have a need to query the end user class for information, for whatever reason.

M: [inaudible]

Michael Baldwin: Yes, our libraries are half of our customers are like OEM customers, so the way we do that, they say what protocol they want to use and then many of them are using our C++ class libraries and statically link.

M: [inaudible].

Michael Baldwin: Our libraries are just, the C++ libraries are statically linked as I'm sure all of you are aware so they'll link right into your application and then the linker works, it just takes the code modules that it needs to link to, so we just do it for a packaging mechanism. Like, for example, our TCP libraries cover TCP, FTP, Simple Mail. POP 3, and Telnet and then when it, since it's just in a .lib, when our users link into it, the actual source modules that are actually utilized are linked in and none of the others are.

M: I was just wondering that if you are using this type of mechanism [inaudible] what happens if I inherit another class [inaudible].

Michael Baldwin: We just make it hidden, it's just removed. There's a technique that you may find useful also and that's one of the fundamental problems from my point of view on C++ is that if you do a straight derivation of classes, you have to include the header files for everything, and that's not appropriate for a commercial-level product to force a user to link with all those header files. So what we do is we do an encapsulation mechanism so that we have our exposed environment that I'll show here in a couple of slides. Then we have a reference to a low level TCP object that has the C WinSock class and has our TCP Sock class. So, since it's a reference or a pointer, and that could be a reference or pointer to anything, we have no need then to distribute the header files for all those base classes which makes our interface cleaner.

That's a very good question. It took me a while to understand that particular limitation of C++.

We're moving along very nicely now. In Section 2 we're going to talk in more detail about the application of C++ mechanisms to communication software development which is the real meat of the story here. I am the developer of all of our libraries and it was non-trivial. The previous product, TCP++ being the precursor, gave us the opportunity to give it one really good try and then a chance to reinvent it. We're going to talk about the protocols here a little bit, too, as we have to before we can talk about the actual software and show pictures of that.

The transmission control protocol. This isn't so different from everything else out there. The marketing going on right now. We'll talk about that at the break or something. TCP is connection-oriented. That means you have to set up the connection like on a telephone. You have to ring the number, the connection happens and then it's point-to-point. That's the only thing it has in common with the telephone. After that it has nothing. But, that is what connection-oriented means.

M: [inaudible].

Michael Baldwin: It's going to be on the CD-ROM and I do have . .

M: [inaudible].

Michael Baldwin: I don't have a script.

M: Based, as far as I understand, on the CD-ROM, they are going to record you and then tie it into the CD-ROM what you are saying and also what I am saying, but would it be possible to receive the [inaudible] of these transparencies using [inaudible].

Michael Baldwin: If you've got a floppy I could just give it to you, but yes, either one.. If you e-mail me and just request the Power Point demonstration, I'll send it over.

A stream means that, it's kind of like no beginning and no end and it just moves along and so you don't know when the data is going to arrive or, actually, when it's going to leave, so it's really stream communications. It also implies there's no record blocking so as the stream moves along it's now blocked up into chunks.

M: There are no frames?

Michael Baldwin: There are no frames. Not that you see. There are frames underneath, but not that you see at this layer which kills us sometimes. Our technical support calls and the guy says, "Man, I sent out 200 bytes, 200 bytes, 200 bytes, 200 bytes and all I got back was the first 200 bytes. That's all I got back." And then your working with tech support, working with tech support and finally comes to find out well it all came back it's just that it came back as a 1,000, right? All in one chunk. He was just assuming, well, if you sent out 200 you get 200. No, it has a tendency to either group or fragment during the transmission and it can do either so you can't depend on that. It's also characterized as bursting communications. Telnet's a good example. You press on a Telnet key, one key, it generates about 40 bytes of header information and one ASCII character and it goes out in the network. If you're doing an FTP transfer it could be several thousand bytes or a megabyte very quickly and saturate a choke point but then it's gone, so that's what bursting means.

M: [inaudible].

Michael Baldwin: We do. It's an option for setting the connect; however, I don't believe it, the no wait option disables Nagle's algorithm which is explained in TCP/IP networking books as if you send us a couple little characters along, the Nagle's algorithm may decide that it will group them up for one packet [inaudible] the network. But on all the WinSock implementations I've seen, although that option is there, I've never seen it. Or if you send a character, it doesn't go. It always goes and I've never found one that didn't as default because when you think about it, so many applications use WinSock for Telnet emulator-type work. When you send a character, it's got to go otherwise just nothing happens and the host always echoes, I mean, typically with a terminal emulator that you'll see, so you want to see that character back on your screen as soon as you hit the button.

Reliable end-to-end communications means that what you send down the pipe is guaranteed to be received in the same order. There's no guarantees on time, but there is data integrity checking and unless you receive an error indication on your end, the WinSock specification says that we have every right to expect that it reached its final destination.

Quick word on two types of connections. An active connection means that there's a client, like an FTP client or a VT-220 client, very typical, makes an active connection out to a host and then what happens at the host, if it's a UNIX host, it accepts the connection, spawns off a process to handle that connection and you're off and running.

A passive connection is where a server accepts that connection and that's available on the WinSock side too and we've built that into our TCP library and our Telnet library so both can be utilized to accept connections on any port.

M: Were you concerned to ringing or dialing a number and answering your phone? Is this [inaudible] analogy?

Michael Baldwin: Yes, that's the analogy. It's ringing the number, other guy picking up the phone and you've got a live connection going on, that's when you're connected. Then data can go back and forth. Then when one guy hangs up the other guy gets the dial tone and knows he hung up, usually.

M: [inaudible].

Michael Baldwin: Well, there are time-out possibilities on establishing a connection that's typically dependent upon the WinSock stack that you are using. What I have seen is typical is
